Overestimation can result when students do not fully understand the demands of the task. Greater task experience informs students of the skills needed to succeed. Calibration also can be affected by instructional and social factors (Schunk and Pajares, 2009). Although instructional practices that provide information about skills required for the task can increase calibration (Schunk, 1981), such practices also can lower it. Students in low-ability groups from which they cannot move may feel demoralized and perform poorly, even though they feel efficacious about learning. Teachers who indiscriminately encourage students (e.g., "Come on, I know you can do this.") without ensuring that they learn skills may produce highly efficacious students who lack the skills to succeed.

The social cultures of schools also may affect calibration (Schunk and Pajares, 2009). Students may perform less than their best – and lower than their self-efficacy would predict – so that they do not become socially isolated as a consequence of being perceived by their peers as overly intelligent.

Self-Efficacy for Self-Regulation

Self-efficacy has been applied extensively to *self-regulation* (or *self-regulated learning*), which refers to learning that results from students' self-generated thoughts, feelings, and behaviors that are systematically oriented toward the attainment of their learning goals (Zimmerman, 2000). Self-regulation involves students' goal-directed activities that they instigate and sustain, such as focusing on task demands, applying effective strategies to learn, establishing productive social and work environments, assessing learning progress, and making strategic adjustments as needed. Developing and maintaining a sense of self-efficacy for self-regulated learning motivates students and promotes their learning (Schunk and Usher, 2011).

Zimmerman (2000) developed a self-regulated learning model that highlights the role of self-efficacy (Figure 3). This cyclical and recursive model includes three phases: forethought, performance, and self-reflection. The *forethought* phase involves processes students engage in prior to learning and includes motivational beliefs and task analysis. Key motivational beliefs are self-efficacy, outcome expectancies, intrinsic interest, and goal orientations (reasons why students want to learn). Task analysis includes goal setting (short- and

long-term goals) and strategic planning, or deciding what methods to use. Although each of these processes has been shown to be related to achievement, self-efficacy is a strong predictor and affects goal setting and strategic planning (Schunk, 2012; Zimmerman and Bandura, 1994).

The forethought phase initiates the learning activities that occur during the *performance* phase, during which students systematically and actively engage in learning. Key self-regulatory processes are self-control and self-observation. Students exert self-control by using such strategies as imagery, self-instruction, attention focusing, and others targeted at reaching goals (Zimmerman, 2002). Self-observation includes self-monitoring and self-recording learning progress. Students gain progress information from their perceptions and feedback from others (e.g., teachers, peers, parents). Research suggests that students who are highly self-efficacious about their capability to learn sustain their efforts and adapt their performances better than those with lower self-efficacy (Pajares, 2008).

On the basis of their self-monitoring and feedback from others, students form self-judgments and experience self-reactions in the *self-reflection* phase. Self-judgments include self-evaluations and attributions of performance to perceived causes (Schunk, 2012). Self-evaluations are based on performance standards that may derive from previous performances, performances by others (e.g., teachers), or absolute standards (Zimmerman, 2002). Causal attributions may reflect controllable causes, such as strategy use and effort, or uncontrollable ones, such as luck or ability (Weiner, 1985). Students also react to their performances with self-satisfaction and adaptive or defensive responses. Self-satisfaction refers to the level of contentment students feel about their performance relative to a standard or goal. Adaptive or defensive responses include emotional reactions to performances. Students who react defensively exhibit apathy, helplessness, procrastination, and cognitive disengagement for future learning to preserve images of self-worth (Garcia and Pintrich, 1994). Students who respond adaptively make adjustments to subsequent self-regulatory behaviors that may include modifying their motivational beliefs and task analyses.

As a consequence of self-reflections, learners may continue working on the task (i.e., the performance control phase) or return to the forethought phase for new goal setting and planning, thus forming the recursive loop in the self-regulation cycle. Students who are self-efficacious about their self-regulatory capabilities are likely to sustain efforts and persist even when they form negative evaluations (Schunk, 2012). These students may attribute performance to strategy use and effort and make adjustments in the forethought phase as they plan for subsequent learning.

Figure 3 Phases of self-regulated learning. Reproduced from Zimmerman, B.J., 2000. Attaining self-regulation: a social cognitive perspective. In: Boekaerts, M., Pintrich, P.R., Zeidner, M. (Eds.), Handbook of Self-regulation. Academic Press, San Diego, pp. 13–39.

Although self-efficacy is an integral motivational belief in the self-regulatory cycle, it is the development of self-regulatory competence that explains how self-efficacy becomes an internal motivational force behind self-regulated learning. Schunk and Zimmerman (1997) formulated a model of development of self-regulatory competence as consisting of four levels: observation, emulation, self-control, and self-regulation. This is not a stage model in which learners move to the next level after satisfying the criteria of the preceding level. Rather, learners may freely move among the levels while engaged in the same task as they develop increasing self-regulatory competence.

Initially, social models – such as teachers and peers – serve as important sources of self-regulatory behavior and self-efficacy. At the *observation* level, students observe models as they perform actions and learn many self-regulatory processes, such as strategic planning, self-monitoring, and performance adaptations (Zimmerman, 2000). In addition, students may observe models as they receive rewards, such as praise and good grades. These observations vicariously build students' self-efficacy for learning.

At the *emulation* level, students practice the behaviors previously demonstrated by the model and imitate the general pattern or style with assistance from the model (Zimmerman, 2000). Students receive reinforcement from the model and from their own senses and motoric feedback. Students' perceptions of their ability to discriminate and differentiate the self-regulatory processes needed to complete a task, along with the model's feedback, provide them with a sense of competence.

In these first two levels, learners derive information about their self-efficacy primarily from external (social) sources. It is at the third level of *self-control* when students begin to experience self-efficacy from within. Schunk and Zimmerman (1997) describe the self-control level as when learners are able to use strategies independently of the model. Students have internalized what they previously have observed and emulated; however, they are still using the representational patterns of the model to perform behaviors. During this level, students begin to experience self-efficacy internally as they are able reflect upon their capability of matching their work against the standards displayed by the model.

Students have reached the *self-regulation* level when they are able to systematically adapt their performance to different environmental and personal conditions (Zimmerman, 2000). At this level, students are motivated by their self-efficacy beliefs. They now are capable of initiating the use of strategies, making adjustments to behavior based on the situation, and evaluating their performance with the understanding that they are capable of competently making changes as needed. As self-regulated students engage in the three cyclical phases of self-regulated learning, they substantiate their sense of self-efficacy and regulate their thoughts, feelings, and behaviors toward goal attainment.

Teacher Self-Efficacy

Self-efficacy is applicable to teachers as well as students. *Teacher* (or *instructional*) *self-efficacy* refers to personal beliefs about one's capabilities to help students learn (Tschannen-Moran et al., 1998; Woolfolk Hoy et al., 2009). Self-efficacy should influence teachers' activities, effort, and persistence. Teachers with low self-efficacy avoid planning activities they believe exceed their capabilities, do not persist with students having difficulties, expend little effort to find materials, and do not reteach content in ways students might better understand (Ashton and Webb, 1986). Teachers with high self-efficacy are more likely to develop challenging activities, help students succeed, and persist with students who have trouble learning. These teacher behaviors enhance student learning and substantiate teachers' self-efficacy for helping students learn.

Ashton and Webb (1986) found that teachers with higher self-efficacy were likely to have a positive classroom environment (e.g., less student anxiety and teacher criticism), support students' ideas, and meet the learning needs of all students. High teacher self-efficacy is positively associated with teachers' use of praise, individual attention to students, and monitoring students' learning progress, as well as with higher student achievement.

Collective teacher self-efficacy represents teachers' beliefs that their capabilities as a group can enhance students' learning (Henson, 2002). Teachers develop collective self-efficacy when they work collaboratively to achieve common goals (performance accomplishments), learn from one another and have mentors who serve as role models (vicarious experiences), receive encouragement and support from administrators (forms of social persuasion), and work together to cope with difficulties and alleviate stress (physiological indexes). As collective self-efficacy is strengthened, teachers remain motivated to collaborate to improve students' learning. Collective self-efficacy bears a positive relation to teachers' job satisfaction (Caprara et al., 2003).

Future Directions

Researchers will continue to test Bandura's (1997) contention that self-efficacy beliefs can affect virtually every aspect of people's lives – their thoughts, feelings, and actions. One important research issue concerns the generality of self-efficacy. As discussed earlier, researchers have moved away from Bandura's contextual perspective and assessed self-efficacy with measures of greater generality. Decontextualized self-efficacy assessments that lack consistency with the criterion task can distort the influence of self-efficacy. To be explanatory and predictive, self-efficacy measures should reflect the task demands within the domain being analyzed. Evaluating the appropriateness and adequacy of a self-efficacy measure requires making theoretically informed and empirically sound judgments that reflect an understanding of the domain under investigation and its different features, the types of capabilities the domain requires, and the range of situations in which these capabilities might be applied. Self-efficacy measures then can be evaluated for their appropriateness using the level of specificity of their items, the range of task demands that they include, and their correspondence with the outcomes of interest (Bandura, 2006).

Research is needed on the role of self-efficacy at different developmental levels. In assessing self-efficacy, learners must integrate information from the environment, their prior experiences, and their beliefs about the present situation. Such complex cognitive processing may exceed the capabilities of younger children, which can decrease the predictive utility of self-efficacy. Most self-efficacy research has been conducted on older children, adolescents, and adults. Determining how younger children weigh and combine self-efficacy information from different sources will substantiate its relevance for learners of all ages.

There is a need for more research studies using students from different cultures. Most self-efficacy research studies have sampled from students in the United States. Cross-cultural studies will expand our understanding of the operation and generality of self-efficacy. Klassen (2004) reviewed several studies and found that self-efficacy tended to be lower for students from non-Western cultures (e.g., Asian and Asian-immigrant students) than for students from Western cultures (e.g., Western Europe, Canada, the United States). In some cases, the more modest self-efficacy expressed by the non-Western students predicted academic outcomes better than the higher self-efficacy of the Western students. The high level of achievement of Asian students may be a product of socialization practices that promote close parent–child relationships. In these cultures, relational efficacy (i.e., the confidence that students have in their familial and social relations), as well as social support from parents, has a powerful influence on students' academic performance. For these students, the lower levels of academic self-efficacy do not translate into lower academic performance.

Research is needed on self-efficacy as students learn from technology. The explosion of technology in instruction through electronic and distance education shows its potential to foster learning in ways that formerly were unknown (Brown, 2006). Researchers are investigating which strategies are helpful for learning from technology and how to teach students those strategies. Similar research is needed on how learning from technology affects students' self-efficacy for learning. Thus, students' performance accomplishments using technology should help build their self-efficacy. But students also learn through social networking, which suggests that other sources of self-efficacy information (vicarious, persuasive) also can build and sustain self-efficacy and motivation. A better understanding of how use of technology affects students' self-efficacy will have implications for the design of learning activities.

Conclusion

Theory and research support the important role of self-efficacy in learning, motivation, and self-regulation. From instructional and social and environmental sources, students gain information that affects their self-efficacy, and in turn, self-efficacy influences various achievement behaviors. The operation of self-efficacy in education contexts will continue to be clarified as researchers investigate such issues as the

generality of self-efficacy measures, how students' capabilities to process self-efficacy information changes with development, how self-efficacy functions in different cultures, and the role of self-efficacy in learning from technology.

Abstract

Self-esteem has been studied extensively by psychologists, with thousands of empirical articles exploring its potential causes, consequences, and correlates. Despite this considerable attention, disagreements persist over how best to define and conceptualize self-esteem. Most psychologists view it as a global evaluation of the value of the self or self-worth. Self-esteem is also dimensional with 'low self-esteem' and 'high self-esteem' representing the ends of a continuum. Self-esteem's enduring fascination reflects, in part, its associations with important life outcomes, such as psychological adjustment, academic success, physical health, and relationship satisfaction. The extent to which self-esteem actually causes these outcomes, however, remains controversial.

What Is Self-Esteem?

Self-esteem can be conceptualized at global or domain-specific levels. Global self-esteem is an overall evaluation of self-worth, whereas domain-specific self-evaluations reflect self-appraisals within more circumscribed domains (e.g., academic, social, or appearance self-esteem; Shavelson et al., 1976). Global self-esteem and domain-specific self-evaluations are typically positively correlated, raising questions about how they relate to each other. Early conceptualizations – such as that of philosopher and psychologist William James (1890) – suggest that global self-esteem reflects an averaging of specific self-evaluations, weighted by their subjective importance to the individual (Marsh, 1986). It is now clear, however, that domain-specific self-evaluations are also colored by global self-esteem (Brown et al., 2001) such that individuals with higher self-esteem view their specific attributes more positively in part because of their high self-esteem.

Self-esteem is distinguished from self-concept. Self-esteem is most typically viewed as reflecting self-feelings (e.g., 'I like myself'), rather than self-knowledge. The self-concept rather is viewed as reflecting self-knowledge or self-beliefs (e.g., 'I am outgoing,' 'I am smart'). This distinction is not universally accepted, however, and can become blurry (e.g., people have strong feelings about their self-beliefs, such as being heavily invested in seeing oneself as competent; Marsh and Craven, 2006). The self-concept has clear implications for self-esteem. Individuals who possess more positive self-beliefs tend to report feeling better about themselves overall than those with less positive self-beliefs (e.g., Segal, 1988). There are also, however, important indirect links between the self-concept and self-esteem (Showers and Zeigler-Hill, 2006). Early models of the self often viewed it as a single monolithic entity, but more modern conceptualizations typically consider the self-concept to be multifaceted, consisting of a variety of self-aspects defined by such factors as situations, roles, and psychological states of the individual. This multifaceted view of the self-concept highlights the importance of self-concept structure (i.e., how self-concept content is mentally organized) for moderating the connection between self-concept content and self-esteem. Self-concept structure can vary in a number of ways, such as its complexity or the degree to which positive and negative beliefs about the self are integrated with each other versus being compartmentalized. Self-concept structure determines the accessibility of specific self-beliefs, which affects their ability to influence self-esteem (see Showers and Zeigler-Hill, 2012).

Measuring Self-Esteem

Self-esteem is most commonly measured by self-report scales. Because self-esteem is considered to be a subjective judgment, asking people how they feel about themselves is a sensible and direct way to assess self-esteem. For children, the most commonly used self-report measure is Coopersmith's (1967). Self-Esteem Inventory and for adults it is Rosenberg's (1965) Self-Esteem Scale. More recently, Robins et al. (2001) created a single-item self-esteem scale to assess global self-esteem, which simply assesses agreement with the statement, "I have high self-esteem." This single-item measure demonstrates impressively high correlations with longer, more established measures of self-esteem. Other researchers have developed multidimensional measures of self-esteem. Tafarodi and Swann (2001), for example, devised the Self-Liking and Self-Competence Scale to assess distinct dimensions of global self-esteem in order to provide, in their view, a more comprehensive assessment of self-esteem.

People also possess distinct trait and state self-esteem. Whereas trait self-esteem refers to relatively stable and enduring self-evaluations, state self-esteem refers to momentary self-evaluations that can fluctuate across time and situations. The two most common methods for assessing state self-esteem are Heatherton and Polivy's (1991) State Self-esteem Scale and MacFarland and Ross' (1982) state self-esteem assessment. In both scales, respondents are asked to consider their feelings in the present moment. However, in Heatherton and Polivy's (1991) State Self-esteem Scale, test-takers report their self-evaluations in three domains: appearance, performance, and social acceptance. The items reflect

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25090-3

cognitive evaluations in each of these domains, such as 'I feel unattractive.' In contrast, the state self-esteem measure developed by MacFarland and Ross (1982) asks respondents to indicate how much certain emotional terms describe their present feelings. Some of these emotional terms represent low state self-esteem (e.g., 'shame') whereas others represent high state self-esteem (e.g., 'pride').

Implicit Self-Esteem

Self-esteem has traditionally been studied in terms of explicit self-esteem – fully conscious, deliberative self-evaluations that are measured by self-report scales. This approach to studying self-esteem may be limited, however, because people may be unwilling or unable to report all aspects of their self-evaluations (Greenwald and Banaji, 1995). Accordingly, researchers have developed several nonreactive or implicit measures of self-esteem, including the Name-Letter Task (Koole et al., 2001) and a self-esteem variant of the Implicit Association Test (IAT; Greenwald and Farnham, 2000). The Name-Letter Task is premised on the observation that people value things associated with themselves, and so people tend to like the letters of their name, particularly their initials, more than people whose names do not share those letters. The IAT examines people's reaction times in associating positive and negative stimuli with the self. Some theorists suggest that implicit self-esteem, as assessed by these measures, reflects a construct that is distinct from explicit self-esteem with unique implications for psychological functioning (see Zeigler-Hill and Jordan, 2010). Implicit self-esteem is considered to be relatively automatic, associative, uncontrollable, and intuitive in nature. Implicit self-esteem, in combination with explicit self-esteem, predicts important psychological outcomes, such as defensiveness and aggression. Some researchers have questioned the validity of implicit measures of self-esteem, however (Buhrmester et al., 2010).

The Importance of Self-Esteem

Relation of Self-Esteem to Important Life Outcomes

Interest in self-esteem began to build steadily during the 1970s as research began to emerge suggesting that low self-esteem was linked to a variety of social problems such as drug abuse, unemployment, academic underachievement, and violence. The 'self-esteem movement' was in full swing by the 1980s as exemplified by the California Task Force to Promote Self-esteem and Personal and Social Responsibility (1990), which focused on raising the self-esteem of the citizens of California in the hope that this would reduce the social problems plaguing California at that time. Various self-esteem enhancement programs have been implemented over the years but they have not had the sort of benefits originally envisioned by the self-esteem movement. There continues to be intense debate about the role of self-esteem in important life outcomes, with some researchers arguing that self-esteem is important for productivity and well-being (e.g., Swann et al., 2007) and others arguing that it has severely limited value (e.g., Baumeister et al., 2003).

Associations with Psychopathology and Well-Being

Self-esteem is closely linked with psychopathology. This connection is evident in the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5; American Psychiatric Association, 2013), which contains various references to self-esteem and terms that are related to self-esteem (e.g., 'grandiose sense of self-importance'). Low self-esteem is included as a diagnostic criterion or associated feature for a variety of disorders including major depressive disorder and bulimia (see Zeigler-Hill, 2011). There are two primary models concerning the connection between low self-esteem and psychopathology. The first model is the 'vulnerability model of low self-esteem,' which suggests that low self-esteem serves as a risk factor for psychopathology. The second model is the 'scar model of low self-esteem,' which argues that low self-esteem is a consequence of psychopathology rather than one of its causes.

Self-esteem is also consistently related to subjective well-being: people with higher self-esteem report greater life satisfaction and happiness than those with lower self-esteem (Baumeister et al., 2003). Moreover, people with lower self-esteem experience more negative moods and fewer positive moods than those with higher self-esteem (MacDonald and Leary, 2012). Some have argued that the greater well-being reported by higher self-esteem individuals might be derived from their tendency to rely on more effective coping mechanisms and their tendency to see the world more optimistically (Baumeister et al., 2003). However, the link between self-esteem and well-being might not be so straightforward. For one thing, the association between self-esteem and well-being seems influenced by cultural variables. For example, the link between these variables is stronger in individualistic cultures (e.g., United States) than in collectivist cultures (e.g., China; Diener and Diener, 1995), suggesting that high self-esteem is not universally tied to greater life satisfaction.

Associations with Physical Health

People with higher self-esteem report greater physical health and an enhanced ability to recover after illnesses compared with those with lower self-esteem (see Stinson et al., 2008). Though it may be tempting to conclude that being ill reduces self-esteem, the causal relationship appears to go in the other direction. There are three main reasons why lower self-esteem might lead to health detriments. First, people with lower self-esteem are less likely to engage in behaviors that promote physical health (e.g., Smits and Kee, 1992), and thus their habits tend to undermine good health. Second, lower self-esteem individuals' physiological experience of stress is apt to erode their physical health. Specifically, lower self-esteem individuals are more likely to experience elevated and prolonged cortisol levels after stress (Pruessner et al., 1999), which might explain why they suffer greater health problems after periods of stress. Third, lower self-esteem might lead to detriments in physical heath because low self-esteem individuals experience poorer quality interpersonal relationships (Stinson et al., 2008). Positive, supportive relationships foster more optimal physical functioning (e.g., lowered cortisol levels). Lacking such relationships may thus predispose lower self-esteem individuals to suffer poorer physical health.

Associations with Academic and Career Success

Is self-esteem associated with success? Most research investigating this question has focused on performance at school and work. In the case of academic performance, people with higher self-esteem report somewhat greater academic success than those with lower self-esteem (Hansford and Hattie, 1982). This partly reflects the fact that high self-esteem predicts the subjective experience of academic achievement (i.e., individuals with higher self-esteem perceive themselves to be better students) but is not strongly related to objective indicators of academic achievement such as grade point average (Baumeister et al., 2003). In addition, mounting evidence suggests that the association between self-esteem and academic performance may be driven by the association of each of these variables with intelligence, family background, and academic achievement in earlier grades (e.g., Maruyama et al., 1981). For example, being more intelligent seems to lead to both greater academic success and higher self-esteem, and thus, the association between self-esteem and academic performance is actually spurious.

Higher self-esteem is also associated with greater success at work. Research suggests, however, that self-esteem is a consequence, not a cause, of performing well at work (Pierce and Gardner, 2004). In their review of this literature, Baumeister et al. (2003) concluded that although self-esteem does not directly lead to better job performance, those with higher self-esteem might still perform somewhat better in the work force. Backing this view are several experimental studies revealing that higher self-esteem individuals exhibit better coping skills that would directly relate to occupational performance. For instance, higher self-esteem individuals are more likely to persist on difficult tasks than lower self-esteem individuals, especially when such persistence is likely to be rewarded. Pierce and Gardner (2004) suggest that organization-based self-esteem (i.e., self-appraisals as a 'good' organizational member) and job performance have a reciprocal relationship: Self-esteem is enhanced by success on the job and this enhanced self-esteem contributes to positive organizational behaviors.

Associations with Crime, Delinquency, and Aggression

Is self-esteem associated with detrimental behavior, such as delinquency, crime, and aggressive behavior? Although much of the research to date has produced conflicting findings, recent longitudinal studies provide a more rigorous test of the causal association between self-esteem and destructive behaviors. This research demonstrates that lower self-esteem is associated with self-reported delinquent behaviors and that these reports are corroborated by students' teachers (Donnellan et al., 2005). Importantly, when these researchers assessed delinquent behavior 2 years later, those with lower self-esteem were again more likely to engage in negative behaviors than their higher self-esteem counterparts. Criminal behavior seems to follow the same pattern: Having lower self-esteem in adolescence predicts a greater propensity to engage in criminal behavior in adulthood (Trzesniewski et al., 2006). For both delinquent and criminal behavior, controlling for other variables known to be associated with these behaviors does not alter the strength of self-esteem's predictive power nor does self-esteem seem to be a consequence of engaging in delinquent or criminal acts.

If lower self-esteem is linked with increased delinquent and criminal behavior, it seems logical to conclude that lower self-esteem should be associated with aggressive behavior. Indeed, an impressive longitudinal study of adolescents suggests that this is the case (Donnellan et al., 2005). However, laboratory experiments have demonstrated a more complex relationship between self-esteem and aggression. Baumeister et al. (1996) conclude that it is actually people with higher self-esteem who will act more aggressively than individuals with lower self-esteem but only when their positive self-views are threatened. Numerous studies both in and outside the lab have confirmed this view: people with higher self-esteem and narcissists who report excessively high self-esteem are more likely to aggress against others than their lower self-esteem counterparts when self-views are threatened.

The Protective Function of Self-Esteem

People with high self-esteem handle negative events better than those with low self-esteem. In particular, individuals with lower self-esteem experience more prolonged distress after negative events such as failure or social rejection (Brown, 2010). In fact, Brown suggested that "high self-esteem functions primarily to enable people to fail without feeling bad about themselves" (Brown, 2010: p. 1389). Self-affirmation theory suggests one reason why this might be the case. It argues that people can maintain their self-esteem in the face of negative outcomes by affirming their positive qualities, even in unrelated domains (e.g., a person rejected romantically may console himself with his occupational success). Because people with high self-esteem perceive themselves positively in more domains than low self-esteem people, they have more psychological resources on which to draw when their self-esteem is threatened (Spencer et al., 1993). Indeed, when confronted by failure, high self-esteem people are more likely to spontaneously focus on their personal strengths and suppress thoughts of their personal weaknesses, compared to low self-esteem individuals (Dodgson and Wood, 1998). Self-esteem may even protect people from the anxiety that can stem from the knowledge of one's own mortality. Humans have the arguably unique capacity to understand that they will die one day. This knowledge creates the potential for intolerable anxiety. Terror Management Theory, however, posits that self-esteem is part of a psychological system that allows people to cope with existential anxiety (Pyszczynski et al., 2004). According to Terror Management Theory, people construct worldviews – culturally specific ways of understanding the world and our place in it – to create a sense of stability and meaning and offer the possibility of symbolic immortality. In this view, high self-esteem results when people believe they are living up to the standards prescribed by their worldviews (i.e., when they view themselves as being 'good' people). Self-esteem thus serves an anxiety-buffering function. Consistent with Terror Management Theory, people with higher self-esteem experience less anxiety, are less prone to deny their vulnerability to early death, and respond less defensively to reminders of death.

The Role of Self-Esteem in Interpersonal Relationships

Self-esteem is rooted in interpersonal and social functioning. Indeed, mounting evidence suggests that self-esteem is best

defined as a 'sociometer' or gauge of social acceptance and relational value (see MacDonald and Leary, 2012). From this perspective, self-esteem is not merely a consequence of interpersonal functioning but drops in self-esteem triggered by rejection serve to alert people to act to repair social relationships. In support of this theory, rejection consistently leads to drops in state self-esteem and poor social relationships lead to reduced trait self-esteem over time. As such, lower self-esteem individuals experience more loneliness, report less social acceptance and support from others and see their ongoing relationships as being of poorer quality relative to those with higher self-esteem.

Do lower self-esteem individuals create their poor relationships? The answer to this question is rather complicated. On the one hand, lower self-esteem individuals may report poorer social ties simply because they tend to see the world more negatively in general (Baumeister et al., 2003). From this perspective, underreporting the quantity and quality of relationships may simply stem from their tendency to see everything in a more negative light. In support of this argument, several studies have reported that self-esteem is unrelated to actual acceptance from others. For instance, Campbell and Fehr (1990) asked participants to engage in a series of first-meetings and report their perceptions of how much their interaction partners liked them and how much they liked their interaction partners. Although lower self-esteem individuals reported lower perceptions of acceptance than higher self-esteem individuals, actual liking was unrelated to self-esteem. Lower self-esteem individuals are also apt to miss indicators of acceptance from dating partners. For example, people with lower self-esteem believe their romantic partners see them more negatively than they actually do and they are less likely to see the support that is provided by a romantic partner after a difficult self-disclosure (see MacDonald and Leary, 2012). Some theorists have argued that it is not simply a matter of lower self-esteem individuals neglecting the positivity coming from their romantic partners. Rather, low self-esteem individuals might actively discount their romantic partners' efforts, assuming that they are insincere attempts to appease them rather than being genuine gestures of caring (Lemay and Clark, 2008).

On the other hand, however, self-esteem may indeed be linked with actual behaviors that affect the quantity and quality of social bonds. For example, the partners of those with lower self-esteem report experiencing less relationship satisfaction and commitment than those partnered with higher self-esteem individuals (Robinson and Cameron, 2012), suggesting an actual behavioral difference between such relationships. Murray et al. (2006) outline how self-esteem differences in social behavior may unfold. According to their risk regulation theory, situations of risk or threat elicit a motivational conflict between the desire to protect the self from possible rejection and the desire to achieve greater closeness with another person. In such situations, lower self-esteem individuals will behave in a self-protective manner whereas higher self-esteem individuals, who have greater resources to cope with disappointment, will behave in a more relationship-promoting manner. Research has supported these claims in both ongoing romantic relationships and initial interactions with a potential romantic interest. For example, self-esteem differences in likable behavior and perceptions of acceptance from an attractive person are only observed when the risk of potential rejection is present and when such risk is removed, self-esteem differences disappear or reverse (Cameron et al., 2010). Thus, when risk is relatively low, self-esteem appears to be unrelated to interpersonal outcomes but when interpersonal risk is high – as may often be the case in romantic relationships – lower self-esteem individuals behave in a manner that impedes or harms their interpersonal bonds. Thus, risk regulation theory not only predicts the actual interpersonal behaviors of those with lower and higher self-esteem but may also explain the conflicting findings in this literature.

The Pursuit of Self-Esteem

People generally appear to be strongly motivated to achieve or maintain positive self-views. They display a variety of cognitive biases and behavioral tendencies – such as attributing successes to ability but failures to bad luck – that seem calibrated to promote self-esteem (Campbell and Sedikides, 1999). People may be fundamentally motivated to see themselves as essentially moral and competent individuals, and a number of deleterious human tendencies may serve this goal, including closed-mindedness, rationalizing decisions, and prejudice (Sherman and Cohen, 2006). Indeed, if people have an overall positive sense of self-esteem affirmed (e.g., by reflecting on an important personal value), they display fewer of these self-serving tendencies; they are, for example, more open-minded and less prone to rationalization. Perhaps as a consequence of pervasive self-serving biases, most people have 'positive illusions' or somewhat unrealistic positive self-views (Taylor and Brown, 1988).

Is the pursuit of high self-esteem adaptive? Positive illusions may foster greater psychological well-being (Taylor and Brown, 1988), but this point remains controversial. Indeed, some theorists suggest that pursuing self-esteem is costly (Crocker and Park, 2004). Self-determination theory posits that people have fundamental needs for competence, relatedness, and autonomy that must be fulfilled in order for people to thrive (Deci and Ryan, 1995). From this perspective, the pursuit of self-esteem (which is seen as a common motive but not a fundamental need) can have negative psychological consequences because it interferes with the fulfillment of basic needs. Consistent with this possibility, students whose self-esteem depends on their academic achievement (i.e., whose feelings of self-worth plummet when they perform poorly in school) are more interested in doing well in exams than in mastering the course material (Crocker et al., 2003). As a consequence, they may have less intrinsic interest in learning.

Fragile Self-Esteem

Actively pursuing self-esteem might thus have negative consequences. In addition, not all high self-esteem is equally beneficial. There is increasing recognition that high self-esteem is heterogeneous, that individuals who report having high self-esteem are not all equivalent psychologically (Kernis, 2003).

An influential distinction has been that between secure and fragile forms of high self-esteem (Jordan and Zeigler-Hill, 2013). Secure high self-esteem is viewed as being well-anchored and stable. Individuals with secure high self-esteem acknowledge their shortcomings yet accept themselves nonetheless. Fragile high self-esteem, in contrast, is viewed as inflated, vulnerable to threat, and in constant need of validation. Individuals with fragile high self-esteem are preoccupied with affirming their tenuous positive self-views and are prone to be defensive and aggressive. To distinguish between secure and fragile self-esteem, researchers have relied on three primary indicators: whether high self-esteem is unstable, contingent, or paired with low implicit self-esteem (Kernis and Paradise, 2002). High self-esteem that is unstable fluctuates markedly across time and contexts. There is a great deal of evidence that people with unstable high self-esteem are more defensive and aggressive than those with stable high self-esteem. Contingent self-esteem depends on meeting specific standards or expectations in self-relevant domains and available evidence (though limited) links it to defensiveness. Lastly, among individuals who report having high self-esteem (i.e., have high explicit self-esteem), those with low implicit self-esteem are more defensive and self-enhancing (see Jordan and Zeigler-Hill, 2013).

Where Does Self-Esteem Come From?

Etiology

Given the importance of early childhood experiences for shaping how individuals view themselves, it seems quite likely that these early experiences will be associated with self-esteem. Consistent with this possibility, DeHart et al. (2006) found that the self-esteem levels of individuals in early adulthood were associated with their memories of how their parents interacted with them as children, an association corroborated by the parents' recollections. Beyond parenting styles, it is also possible that the family environment may influence self-esteem through the genetic contributions of both parents (Neiss et al., 2002). Self-esteem appears to be connected to temperament such that those who are predisposed to experience negative affect or to be more reactive to stressful life events may be more likely to develop lower self-esteem if they are exposed to aversive social environments during early childhood. The foundation of self-esteem appears to be established during childhood but feelings of self-worth can certainly change throughout the life span as individuals experience positive and negative life events (e.g., acceptance and rejection).

Developmental Changes

Individuals with relatively high levels of self-esteem early in their lives tend to report higher levels of self-esteem than their peers throughout their lives (Trzesniewski et al., 2013). Despite this consistency across individuals, average levels of self-esteem have been observed to change systematically across the life span such that feelings of self-worth are relatively high during childhood before dropping precipitously at the beginning of adolescence (Robins et al., 2002). Self-esteem follows a quadratic (inverted-U) trajectory from this point such that it increases throughout adolescence, young adulthood, and middle adulthood before reaching its peak around 50–60 years of age and then declining in old age (e.g., Orth et al., 2012).

Origins of Self-Esteem

One might ask why people have self-esteem at all. What are its potential evolutionary origins? The sociometer model posits that self-esteem evolved as a gauge or index of social inclusion such that low self-esteem serves as a signal that one is at risk of exclusion and must take action to maintain social acceptance (Leary and Downs, 1995). Consistent with the sociometer model, feelings of self-esteem are closely related to feelings of social inclusion such that state self-esteem decreases when people are socially excluded (Leary et al., 1995). Kirkpatrick and Ellis (2001) extended the sociometer model by arguing that self-esteem actually represents the operation of a suite of psychological mechanisms (or sociometers) that evolved to meet the distinct adaptive challenges associated with mate selection, establishing and maintaining status and rank, and the formation of alliances. Within this model, humans evolved different, functionally specific self-evaluations to monitor their mate value, social dominance, prestige, inclusion, and collective worth.

Status-tracking models of self-esteem – such as the sociometer model – have focused on the influence that perceived standing has on the self-esteem of the individual without addressing the possibility that self-esteem also influences how others perceive the individual. That is, self-esteem may serve as an interpersonal signal (see Cameron et al., 2013, for an extended review of this issue). The status-signaling model of self-esteem (Zeigler-Hill, 2012) addresses the signaling property of self-esteem by suggesting that the feelings of self-worth exhibited by individuals are likely to influence how they are perceived by others in their social environments. This basic effect has been observed in a variety of studies showing that manipulating the ostensible self-esteem level of a target influences how he or she is evaluated on dimensions such as romantic desirability (Zeigler-Hill and Myers, 2011).

Improving Self-Esteem

Self-esteem is considered to be an integral component of various forms of psychotherapy including humanistic therapy, motivational enhancement therapy, and cognitive-behavioral therapy (Mruk and O'Brien, 2013). For example, cognitive-behavioral therapy influences feelings of self-worth by focusing on the recognition and correction of cognitive errors such as all-or-none thinking, overgeneralization, and selective attention to negative life experiences. A large number of laboratory manipulations have been developed to temporarily alter self-esteem levels, with some of these techniques using classical conditioning (Baccus et al., 2004) or asking individuals to attend to positive stimuli (i.e., smiling faces) while ignoring negative stimuli (i.e., frowning faces; Dandeneau and Baldwin, 2004). Although an array of self-esteem enhancement programs have been implemented in schools, the utility of these programs remains uncertain.

Abstract

The concept of self-organization in social science is reviewed. In the first two sections, some basic features of self-organizing dynamical systems in general science are presented and the origin of the concept is reconstructed, paying special attention to social science accounts of self-organization. Then, theoretical and methodological considerations regarding the current application of the concept and prospective challenges are examined.

Self-organizing dynamical systems (SODS) is a concept widely used in the physical and life sciences, with promising applications in social science. Because there is an extensive literature on the topic elsewhere, the focus here is on the prospective use of the concept in social science, understood in a broad sense to be those disciplines that study any manifestation of human behavior.

Basic Features

Several definitions of self-organization can be found in the literature. Although a consensual transdisciplinary definition is unlikely, and maybe also undesirable, some features are shared by most accounts of the concept.

Pattern Formation

The basic idea of self-organization relates to pattern formation. Identification of patterns, however, is not a straightforward matter. Observational criteria such as the geometric distribution of cell states in a fractal serve well as a starting point for simple systems. For more complicated systems like societies, robust criteria regarding organization are required. Capturing that meaning with a definition that does not then require further qualification is very difficult. Self-organization has been framed as an increase in coordination, a reduction in entropy, a movement from simple to complex structures, or a decrease in degrees of freedom. It is not yet clear to what extent these criteria can be translated from their original domains to social science and if they can provide any insightful information about traditionally studied social processes, such as normalization, stratification, specialization, etc.

Whether or not a change in self-organization can be quantified is another key question. The more clearly the level of organization in a system is quantified, the more objective the organizational criteria devised become. In social science, however, full quantification is considered difficult or unlikely. Measurement in many cases relies on qualitative or stylized perceptions of the system. The observer's subjective point of view and interpretation is important. Comparative studies have shown, for example, that traditional societies have subsystems with high levels of organization and complexity, and, yet, because of the past observers' biases and prejudices, for a long time these societies were understood to be simple and wrongly labeled 'primitive.'

Autonomy

Autonomy covers the 'self' in self-organization. Any change in a self-organized system must come from inside the system, and must be caused by the many individual entities, or interactions between these entities, rather than from a single controlling or external force. This does not require that the system be closed, with no input from outside, but rather that any input must not be a controlling force. Social systems pose two particular challenges for this feature of self-organizing systems. First, there are asymmetric power relations between and within levels; second, the boundaries of social systems and subsystems are difficult to draw. Regarding the former, humans are intentional actors and can have designs on controlling or influencing a system through individual or institutional action, for example, by the implementation of public policy. Regarding the latter, setting the system and subsystem boundaries is crucial. The outside and inside of the system need to be clearly identifiable in order to make sure any controlling force is not ignored via undue manipulation of the boundary of the system. However, social science often ignores or is vague about boundaries, both for theoretical and methodological reasons. For example, it is common to model countries' economies as closed systems, ignoring all the external influence, because it is easier methodologically. Furthermore, it can be difficult to draw a boundary around even simple social subsystems. The rules that define the membership of social groups or who exactly is to be included in a 'family' can be vague and contested.

Robustness and Resilience

Robustness and resilience are features usually ascribed to SODS. Although these two terms are often used interchangeably, robustness refers to a system's ability to resist change, whereas resilience refers to a system's ability to adapt or recover from change. Both concepts could be used for the same process, depending on the observer's perspective, meaning it is not always clear whether a social system is robust or resilient. For

example, an economy may experience an external shock in the form of a natural disaster, but no major changes in its structure may be observed. It will be unclear whether this is because it resisted the shock or adapted to it. It is difficult to devise objective criteria to quantify the difference between the two.

Dynamics

Dynamical systems are those systems whose main features or properties are not time invariant. SODS change over time and these changes are given by the nonstatic character of the constitutive elements and relations. Change in SODS is usually the result of path-dependent processes, meaning that the system's future states are highly dependent on past states. This is why understanding the dynamics is important. However, the exact role that the concept of dynamics plays in the study of SODS is dependent on the conceptualization of self-organization. Some portray self-organization as leading to an equilibrium or attractor state, whereas others highlight the processes and dynamics of a system. Take the case of cooperation. The focus might be on the process of interaction that allows for the emergence of a structure of cooperative behavior in the first place or on the changes produced by this structure in the long run, for example, the propagation of cooperative behavior. In the first approach, the system dynamics lead to and maintain a state of self-organization, whereas in the second case, the organization generates the system's dynamics. Although not philosophically incompatible, the two views focus on different aspects of the dynamic of self-organization.

SODS can include both positive and negative feedbacks loops. The former creates a stabilizing effect that maintains the current system properties, whereas the latter destabilizes systems by creating self-reinforcing processes. Feedback may have thresholds around which the behavior of the system will be significantly different. The effects on organization may not be gradual, but occur in a modular, step-wise, or hierarchical fashion.

Historical Development

Ideas similar to the concept of self-organization can be traced back to many important figures in Western thought. Yet, after the first explicit reference in Kant's *Critique of Judgment*, the concept did not play a major role in science until it was picked up by Ashby (1947) in the context of cybernetics. He used the concept in his discussion on whether it was possible to produce self-induced change in the organization of a machine.

The contemporary use, however, is the result of developments in analytical tools, technology, and theory. Analytically, it required the development of a nonlinear mathematical framework, for it avoids the stringent formalization assumptions of traditional scientific methods (Strogatz, 1994). The application of nonlinear mathematics to the study of dynamical systems has benefited greatly from an increase in computational capabilities. Technological developments in hardware and software have allowed researchers to process large amounts of data and also to find numerical solutions for nonlinear equations. Important developments in information theory and processing have also played a significant role, as they provided insights about the context, conditions, prospects, and limitations of information processing in artificial and natural systems. The idea of cellular automata, for example, has played a major role in the understanding of self-organizing dynamics (e.g., Wolfram, 1994; Mandelbrot, 1982).

The key theoretical development was the articulation of a comprehensive theory of systems, building on important efforts such as von Bertalanffy's (1969) work on general system theory. The concept of self-organization is currently studied as part of the wider framework of complexity science (Bar-Yam, 1997). Social science, as a general area of inquiry, has not contributed much to complexity science nor, with some exceptions, has it benefited much from these developments.

There have been cases of straightforward translation of the complexity framework to social science, especially in disciplines with a preference for formal methods, such as economics. In addition, some areas have used ideas and methods from complexity science, adding some social theory into the mix, to form a subdiscipline that has become known as computational social science (Gilbert, 2010). These efforts, however, have not led to a general growth in interest in these topics or to a proper cross-fertilization with the mainstream.

Some of the concepts associated with complexity and self-organization have also been used independently in social science. For example, Luhmann's (1995) system theory uses concepts such as self-reference and autopoiesis, but frames them in a particular understanding of symbolic communication that is not compatible with all aspects of the current complexity framework. In other cases, the connection has been based on discursive rather than scientific criteria. For example, connections established between deconstruction and chaos theories were not grounded on methodological similarity, but on the way these approaches were said to challenge the scientific status quo (Cilliers, 1998).

Despite this lack of connection with the contemporary usage in complexity science, it could be argued that social science has approached the problem of self-organization in its own way. The notion of self-organization has been applied both to the case of separated entities that become joined after certain dynamics and to the case of the rearrangement of joint entities. The question about the formation of the State that has puzzled social researchers since the first contractualists in the seventeenth century is an inquiry about self-organization because the 'contract' has mostly played a metaphorical role. Likewise, questions about 'good' organization have been a matter of interest for social scientists since the emergence of the disciplines. In economics, Adam Smith's 'invisible hand' refers to the manner in which the economy organizes itself to maximize social welfare, although each economic agent is only trying to increase his or her own welfare. This notion of self-organizing optimal distribution has dominated the development of the discipline and has had huge importance in political discourse. Likewise, the first sociologists focused their theorizing on how societies could or were coping with the effects of the demographical changes that followed the transition to modernity. Weber's 'iron cage,' for example, was understood as providing 'good' organizational principles regarding power and authority in modern societies.

Not all social theories are articulated in the same terms or grounded in the same philosophical foundations. Some of

them are clearly in opposition to the idea of self-organization. Yet, examples of self-organizing dynamics can be found in almost every social setting. Sometimes, the reference is hard to identify because it is surrounded by narrative and metaphors, as with the case of the 'social contract.' At other times, the idea has unnecessary or conflicting philosophical connections. Nonetheless, for most of these accounts, the links with complexity theory can be traced and a reformulation in terms of a complexity theory framework is possible.

Theoretical Considerations

When dealing with self-organizing social systems, one needs to avoid teleological explanations of social processes, that is, explaining social processes in terms of societal goals or final causes. The most well-know teleological approach in social science is functionalism. This approach started as a biological analogy, with social changes studied in terms of function and dysfunction. The teleological character was given the assumption of a functional end state, such as social integration. A key criticism, stressed by conflict theorists, is that there is no reason why integration should be a natural result of the organizational process. It is questionable whether any final aim or goal of a social system can be identified. Although explicit teleological formulations are uncommon now, some forms of teleology still persist implicitly in more formal reasoning, such as causal explanation.

Removing teleology is just the first step. The 'self' in self-organization when studying social phenomena requires more consideration. Societies have several levels of organization. They have cultures, fashions, markets, legal, moral, and social norms and spatial manifestations (towns, cities, farmland, etc.). If self-organization means only that a system is not externally organized, societies can easily be considered self-organizing. However, if self-organization is defined as a system where order or coordination increases without an agent either inside or outside the system producing this order, some caveats arise. Some parts of social systems come about or are shaped by the purposeful or intentional behavior of individuals or institutions within the system. For example, markets are usually understood as self-organizing. However, most markets are regulated (and thus organized) by externally imposed legal rules. Likewise, an institutionally explicitly sanctioned Highway Code affects the organization of highway traffic. In both examples, the autonomy of the subsystem can be questioned.

These issues can be resolved in different ways. One option is to dismiss purposeful or intentional behavior by deeming it unimportant for the overall behavior of the system. By following this approach, social science could benefit from an almost straightforward application of the framework for the analysis of SODS developed in disciplines outside the social realm. This is the path taken by disciplinary areas such as sociophysics (Galam, 2012) and econophysics (Mantegna and Stanley, 2000). Another option is to consider agents' intentions as having local effects only. This is the approach taken by social theories highlighting the effect of unintended consequences of individual purposive action. A third option is to consider individual intentions as socially determined. This view is commonly associated with macro or structural approaches in social science.

The underlying differences between these options, and many others that could be found in between, stem from the different ways that social scientists have approached core philosophical dualisms, such as micro–macro, agency–structure, and subjectivism–objectivism. Although philosophical consensus around these issues is unlikely, operationalization can help advance the discussion in significant ways. Where all these theories converge, despite the differences in philosophical foundations, is in the identification of 'action' as social science's primary epistemological building block. The operationalization of action is important for the study of SODS. A bottom-up approach is distinctive in the contemporary study of complex systems. It is the interaction between a system's components that gives rise to self-organizing dynamics. Human actors are the key component of social systems and individual action is the key element of social interaction.

Methodological Considerations

Questions about operationalization are solved in science through modeling. Models play a major role in science because they make phenomena accessible for scientific treatment. A scientific model is a simplified representation of particular features that makes a phenomenon more easily understandable and measurable. Most social phenomena have a scale and level of complexity that makes them difficult to understand by direct observation and experimentation, and models can be useful for the same reasons as in science. Moreover, in social science, there are technical or moral reasons that often prevent social scientists from experimenting directly on the social world, while experimenting with the corresponding models is possible.

In what regards to human action, scientific models of self-organization deal mostly with the subject of intentionality. Human beings perform actions based on particular beliefs, attitudes, desires, and purposes. The cognitive foundations, decision heuristics, and contexts for all these can be quite different. Yet, in order to be formalized and operationalized, intentionality has to be simplified and detached from its symbolic and material needs and implications. The intention or meaning attached to human action is articulated in terms of reflexive capabilities. Individual action is formalized as a reactivity–reflexivity pair. Humans share reactivity with other basic entities of complex systems. This is understood as the basic capacity to respond to external stimuli. Reflexivity is where social methods usually differ from other disciplines. In models of social phenomena, reflexivity is associated with the articulation of decision heuristics. The complexity of these decision heuristics and the general role of reflexivity in the model depend on the level of detail and realism of the cognitive structure attached to it.

Simple atom-like models, such as those typical of econophysics or sociophysics, have no cognitive structure. Behavior in this case is just reactive. In game theory, when strategies such as tit for tat are introduced, actors have a more complex cognitive structure due to the addition of a capacity for memory (e.g., to memorize previous actions). Alternatively, agents can

have very complex symbolic communication including a proper language. At this latter level of development of the cognitive structure, agents can reflect on some of the most complex principles of interaction, such as double contingency. The complexity of the cognitive structure can also be modeled through the nonsymbolic paradigm. For example, in neural networks, complex information processing can transform syntactical structures according to different semantic purposes.

Simulation Models of SODS

Conventional quantitative statistical methods have difficulty in accounting for the dynamical aspects of social phenomena. They have relied mostly on cross-sectional (i.e., single moment in time) analyses, with powerful longitudinal methods developed only during the late twentieth century. Accounting for the processual character of a phenomenon is sometimes not possible because there are not sufficient longitudinal data, or data sets are not compatible, too complex, or unreliable. Some of these difficulties can be avoided by simulation because it allows modeling one process by another process. Simulation has played an important role in the study of SODS because of its focus on the dynamics of the system. The two styles of simulation that have most often been applied to SODS are system dynamics and agent-based models.

System dynamics models consist of sets of equations that can be solved analytically or numerically, depending on the complexity of the phenomenon analyzed. In most cases, the self-organizing character of the phenomenon is determined by a dynamic equilibrium, influenced by the initial conditions and the effect of feedback loops. For example, Martinez Coll's (1986) system dynamics model is a recreation of Hobbes' seminal problem of order. Hobbes' original formulation refers to the way individuals compete for resources with each other in a human group with no rules. The model consists of a set of equations that determine individual strategies regarding the possession and sharing of goods. In the simulation, successful strategies can be inherited, imitated, or learned from others. Self-organization occurs in the model as a result of these adaptive interactions. The results of the model show a convergence of agent strategies, varying according to the strategies' distribution at the beginning of the simulation.

Agent-based modeling uses a different methodological principle. In these models each agent in a model is a self-contained program that can take autonomous decisions according to its perception of the environment. It is considered a promising tool for the exploration of self-organizing dynamics in the social world because it allows for the direct coding of heterogeneous agents that can be set to interact with each other and with an artificial environment as the simulation progresses. System self-organizing properties are generated in agent-based models from the interactions of these autonomous agents without central control. As agents are influenced by their perception of the environment, system properties can in turn influence decisions, potentially producing feedback loops.

Both simulation techniques have their drawbacks. Social science has struggled historically to delineate a theory of properties and measurement. It is not clear whether social variables, such as 'being poor,' have the same character and status as physical variables, such as 'having weight.' Even if they can be considered as variables in the same way as physical variables, it is unclear how to measure them (Michell, 2007). The need to define formally what is being measured and the relations between the measurements imposes limitations on what can be modeled. Equation-based models face challenges in this regard due to the restrictions of mathematical formal language. By relying on computer code, more flexible syntactically and semantically than mathematical language, agent-based modeling bypasses some of the formalization limitations, but faces additional problems regarding the adequacy and robustness of its results, for comprehensive verification and validation techniques are still being developed.

Examples of SODS

There is a plethora of examples of models of self-organizing systems in the social sciences at differing levels of complexity. We describe two examples that conceptualize their social processes as a self-organizing dynamics.

The first example is a simulation model of residential segregation developed in Schelling (1971). Agents of two types are distributed randomly on a checkerboard. An agent can perceive the eight neighboring cells around itself and has a preference about the maximum number of dissimilar agents in its neighborhood, its 'tolerance threshold.' If the number of dissimilar agents is greater than the threshold, an agent is deemed unhappy and will move to a different cell. The selection of the new destination can result from different criteria. In Schelling (1971), the agents move to the nearest spot that satisfies their tolerance threshold, but many implementations of this model relax this movement criterion, letting agents simply move to a random other spot on the checkerboard (see e.g., Wilensky, 1997, 1999). In each cycle of the simulation, each agent moves to a new spot if it is unhappy in its existing one. An agent moving into a new spot changes the existing neighborhood, creating a path-dependent dynamic. This model revealed the existence of a critical and surprisingly low tolerance threshold, at about 30%, above which an initially random distribution of agents converges to a segregated pattern as shown in Figure 1. If the clustering of same colored agents is interpreted as an increase in the organization in the system, this model shows how segregation dynamics can be an SODS. The simple preference of individuals 'not to be in a minority' together with the perception of their direct neighborhood and their possibility to move leads to high levels of clustering and in turn high levels of organization, without any external influence.

The second example concerns opinion dynamics, i.e., patterns of opinions (such as political views) in a population. There are numerous models of opinion dynamics, one of which is the bounded confidence (BC) model of the social influence on an agent's opinion (Hegselmann and Krause, 2002). In the BC model, a person can only be influenced by others who are not 'too strange' or are deemed 'reasonable' by the agent, that is, not differing too much from one's own opinion. Thus, the range of opinions in which an agent has confidence is bounded. The BC model consists of a set of

Figure 1 Schelling's segregation model in (a) the initial randomized spatial distribution and (b) the stable segregated pattern obtained after several iterations at tolerance threshold of 30% (Wilensky, 1997, 1999).

individuals, $i, j \in I$, each of which has a certain initial opinion, given by a real number, $x_i(t_0) \in (0,1)$. The profile of all opinions at time t is

$$x(t) = x_1(t), \ldots, x_i(t), x_j(t), \ldots, x_n(t).$$

Each individual i takes into account only those individuals whose opinions are not too distant, expressed by the interval $|x_i(t) - x_j(t)| \leq \varepsilon$ (confidence interval). The set of individuals that i takes into account at time t is

$$I(i, x(t)) = \{j \mid |x_i(t) - x_j(t)| \leq \varepsilon\}.$$

The opinion of individual i at time $t+1$ is the average of the opinions of those individuals in $I(I, x(t))$. Using this simple specification, the macroscopic dynamics of opinion assimilation can be studied.

If the alignment of opinions is interpreted as an increase in organization, the BC model shows how opinion dynamics can be an SODS. The level of opinion alignment reached is dependent on the size of the confidence interval ε. There are three general resulting opinion profiles: (1) plurality, a range of surviving opinions; (2) polarization, two opinions survive at a relatively large distance from each other; and (3) consensus, only one opinion survives (see Figure 2). There are phase transitions at values of $\varepsilon = 0.15$, above which there is polarization, and at $\varepsilon = 0.25$, above which there is consensus.

Both models show how social process can be modeled as SODS, with the increase in the organization of the system represented by a clustering dynamics. The difference is that the segregation model produces clustering in physical space, while the BC model of opinion dynamics produces clustering in a Cartesian space. The self-organizing dynamic in Schelling's model is the result of agents changing their physical location according to predefined rules of interaction, whereas in Hegselmann and Krause's model, the self-organization occurs because of behavioral change produced by processes of social influence.

Conclusions and Future Outlook

Despite the lack of a consensus about the definition of SODS, the concept provides interesting insights for social science. Concepts such as SODS can help to overcome the limitations of more conventional approaches in addressing process, time, and dynamics.

To develop a more comprehensive framework and definition of SODS, cross-fertilization of theory and methods is needed between mainstream social science and the emerging field of complexity science. As increasingly accessible computational power and improvements to software become available, it will become easier for social researchers to deploy modeling tools that can allow them to simulate and understand the many self-organizing phenomena that one sees in the social world.

Figure 2 Plurality (left), polarization (center), and consensus (right) in the BC model of opinion dynamics (Hegselmann and Krause, 2002). Individuals are arranged along the *y* axis and are color-coded according to their opinion (from y = 0, red, to y = 1, magenta). The *x* axis represents time.

Self-Regulated Learning

Philip H Winne, Simon Fraser University, Burnaby, BC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Learners self-regulate learning when they examine the learning environment and monitor learning processes to inform decisions about managing learning processes. Under the assumption that learners are agents with inherent capability to make and act on decisions, self-regulated learning (SRL) is ubiquitous. Decisions learners make about regulating learning, however, can promote or impede achievement and other valued outcomes. Research on SRL and its roles in education faces multiple challenges. Evidence suggests productive SRL can be fostered through evidenced-based designs for learning activities and environments, by promoting particular beliefs among teachers, and helping learners discover value in education.

Learners in school, on the job, and pursuing their hobbies study a wide range of information – the meaning of terms such as inertia or tempo, differences among political systems and between gasoline and diesel engines, how to prevent backflow in drainage systems, and more. Beyond huge variation in topics, learners also differ enormously as learners. They begin learning with different backgrounds of knowledge. They seek various goals and differ in persistence if challenges arise. Amid a host of individual differences, at least one feature is common. As learners prepare for, engage in, and reflect on learning, they make decisions. Within the broad field of learning science, self-regulated learning, often abbreviated as SRL, encompasses theories about and research on decisions learners make about learning, factors affecting this decision-making, how frequently and easily learners make decisions, and how attributes of these elements relate to other attributes of learning such as motivation and achievement.

Characteristics of SRL

Learning is a process, not a state. Learning involves actions, mostly cognitive but also overtly behavioral, that operate on information in ways learners intend to build knowledge or set a stage for building knowledge. Viewing learning as cognitive operations that learners regulate has several key corollaries (Winne, 2010).

Information is not inherently knowledge but a learner can operate on information to transform it into knowledge. Rehearsing is one common cognitive operation; it involves mentally repeating information, such as a term's definition, or repeatedly performing an action, such as the motions in tying a bowline knot. Another common cognitive operation is translating information into a different format. Drawing a parabola to represent an algebraic expression of a quadratic equation is an example. Choosing operations is a decision that regulates learning. Therefore, SRL is a metacognitive event (Nelson and Narens, 1990) in which cognitive operations and environmental affordances that might be used in learning are the objects of decision-making about how to transform information into knowledge.

A learner's decisions about how to learn are not random choices. Decisions are directed by goals, particular outcomes a leaner forecasts will or very probably will result if a particular pattern of operations is applied. Bandura (1977) labeled this an outcome expectation. Judging the probability that a particular outcome is produced by applying particular operations is different from judging the probability those operation(s) can be carried out. This latter judgment is about capability; it is Bandura's concept of self-efficacy. Thus, SRL is inherently motivational in three senses (Winne and Marx, 1989). First, learners select which goals to pursue. Second, learners choose how to operationalize their pursuit of goals. Third, learners decide how long to pursue a goal that has not yet been achieved. As learners consider these motivationally related choices, they form attributions for outcomes and experience affective reactions. A learner may explain success as due to effort and find other than not in developing knowledge. Having accurately forecast outcomes or succeeded in translating an algebraic expression into a graphical form may satisfy the learner's quest for understanding.

Particular decisions may be motivated by external conditions, such as a parent's promise of reward for a good score on a test or a teacher's warning of extra homework for a poor score. Nonetheless, learners are the ones who choose goals and, given constraints and resources in their environment, how they will seek goals. The additional impact (an economist would say, marginal utility) of various outcomes may have different weights in the learner's system of values. A learner may judge rehearsing more efficient but not as effective as translating as a means to develop knowledge. But a graph may be preferred over algebraic form. That the learner has such choices to make and makes them gives rise to a property called agency. In the process of SRL, the learner expresses agency by deciding how learning unfolds.

In summary, SRL concerns how learners strive to build knowledge by metacognitively monitoring and regulating mental content and factors in the external environment. The objects of metacognitive monitoring include cognition, decision-making, planning, motivation, affect, and emotion. Targets for metacognitive control include: (1) fundamental cognitive operations such as rehearsing or translating, as well as larger-grained learning strategies; (2) motivationally oriented thoughts about reasons for engaging in learning (e.g., mastery or performance goal orientation) and the explanations (attributions) and value(s) of outcomes generated by engaging in

learning; (3) perceptions of feelings (affect, emotion); and (4) factors in the external environment, such as opportunities to obtain help and whether to store information externally in notes. After a stage is set for a learning episode, as the episode unfolds, decisions the learner makes in SRL alter these conditions. SRL is a dynamic process of adaptation in support of learning.

Models of SRL

Models identify and organize key factors at play in a process. Given SRL's wide scope, it is predictable that multiple models have been proposed, first appearing in the late 1980s and early 1990s alongside growth in the wider field of learning science. In differing ways, models of SRL share the characteristics described earlier. But differences among them are important.

Boekaerts' Model

Boekaerts' model addresses "students' ability to select, combine, and coordinate cognitive strategies in an effective way" (Boekaerts, 1999: 447) provided that students perceive real choices or 'alternative action paths' (p. 449) for learning. Paths are shaped by cognitive strategies students believe will develop knowledge, metacognitive knowledge and skills for directing those cognitive strategies, and goals and resources that create conditions within which learners engage with tasks.

Boekaerts postulates two inherent priorities as bases for deciding among action paths. One priority is extending knowledge and skills that expand personal resources for learning and other valued activities. Serving this priority activates a mastery mode in which applying learning strategies spends effort and potentially risks other forms of personal capital, such as self-concept or social standing. The second priority is preserving resources and averting damage to well-being. Serving this priority situates a learner in coping mode where strategies are redirected and opportunities to extend personal resources are set aside. Most learning involves tension between these priorities, motivating prudent SRL.

The hub of Boekaerts' model is an appraising system that weighs real-time information from three sources as a task unfolds. One source is the learner's integrated view of a task's inherent features (e.g., intrinsic cognitive load), instructions and other conditions established by a teacher or peer group, tangible resources (e.g., time, access to information resources), and the social context. A second source of information appraised is the learner's stockpile of knowledge, task specific skills, and metacognitive skills relevant to the task. The third collection of information appraised concerns the student's self, e.g., views about actual and ideal self, motivational elements, and values. The appraisal system weighs this complex, multidimensional bundle of information and assigns priorities to the mastery mode and the coping mode.

Boekaerts' model also describes phases in a learning episode: identifying conditions that bear on the situation, interpreting them, appraising them automatically (because this situation is characterized in a habitual way) or deliberately, setting goals and, finally, engaging with the task. While a learning episode usually unfolds sequentially across phases, a learner may retreat if significant changes arise regarding elements of the situation. Thus, an action path may be revised in the midst of engagement.

Efklides' Model

In Efklides' model of SRL (Efklides, 2011), macrolevel and microlevel factors affect interactions among metacognitive, motivational, and affective processes. Macrolevel factors, also labeled the person level of SRL, are stable characteristics that generalize across tasks, situations, and time. Conventionally, these are traits. Examples are a learner's self-concept and epistemological beliefs. At the microlevel, specific features of a task situated in a particular context interact with person-level factors. The influence of person-level factors recedes as work unfolds, and subjective experience is frequently updated. At the microlevel, topics of metacognition that shape SRL include ongoing thinking, feelings, emotions or physiological states denoting effort exertion during task processing (Efklides, 2011: 7). Because SRL operates in both levels, it is simultaneously a top-down (person) process guided by goals and a dynamic bottom-up (task × person) process. That task × person process successively revises bases for regulating learning as the state of work is updated and, particularly, as the learner subjectively experiences the flow of activity.

Cognition and affect/motivation are foci for regulation in Efklides' model; hence, its name, the metacognitive and affective model of SRL or MASRL. Three kinds of thought contents are distinguished. First, metacognitive knowledge spans what a learner knows about cognition, conditions under which forms of cognition are engaged and the profile of motivational and affective factors associated with task conditions the learner recognizes, and the products constructed in the task. Second, metacognitive experiences are moment-to-moment changes the learner perceives as work unfolds. This includes awareness that something relevant is known even though it cannot be explicitly recalled (i.e., a feeling of knowing), affect arising about the rate and amount of progress, and expectations about whether a particular cognitive tactic might be effective at this point in the task. Third, metacognitive skills are rule-based forms of knowledge that join metacognitive experiences to metacognitive knowledge about controlling how work on a task is organized. An example is a cognitive tactic such as, if the task now seems vague (a metacognitive experience), then review directions for clues about how to proceed (a metacognitive skill).

Efklides posits that SRL has three phases. In task representation, the learner builds a mental representation of a task. This representation is colored by the learner's person-level traits and may differ from an observer's account. Based on this task analysis, cognitive processing is applied to work on the task in phase two. In the third performance phase, a product is generated. Throughout all three phases, as learners monitor metacognitive experiences, adaptions may be made to cognition, metacognition, affect, and effort.

Pintrich's Model

In Pintrich's model (2000, 2004; see also Schunk, 2005), decisions about regulating learning involve factors in four

categories: cognition, motivation, behavior, and context. These factors are addressed over four phases.

In phase 1, cognition generates forecasts about how a learning task may unfold, activates prior knowledge and metacognitive knowledge, and sets goals for the task. Motivational processing focuses on identifying reasons for engaging in this task, i.e., the learner's goal orientation. Other motivational processing judges efficacy for carrying out the cognitive and metacognitive operations perceived essential to do the task, judging the value of and interest in the task's products, and developing an overall judgment of how difficult it will be to complete the task. In the behavioral arena, the learner considers how to allocate time and effort to elements in the task, and how to gather data about progress. Learners also examine whether features of context, such as instructions a teacher provides or social factors, can be regulated during work.

Phase 2 of Pintrich's model is monitoring. In the cognitive arena, judgments of learning and feelings of knowing are rendered. Motivational topics monitored include changes to efficacy expectations, attributions that explain why the task is or is not progressing, and emotional reactions. Having set standards for time and effort to assign the task, learners track these factors to detect deviations. Also, changes to contextual factors are scanned.

Phase 3 is exercising control over factors in each of the four areas. For example, if learning is judged subpar, learners may decide to review content, adjust efficacy expectations, revise the rating of task difficulty, and search for supplementary materials or seek out help.

In the fourth phase of Pintrich's model of SRL, learners react to and reflect on their experiences with the task overall. Again, each category of regulation is considered. Cognitively, learners may realize they might have fared better by activating a broader sample of knowledge related to the task versus 'diving in.' Motivationally, they may attribute low activation of knowledge as explaining why the pace of work was slow, suggesting more effort would have more satisfying results. In the behavioral arena, time may be deemed more important than first considered and, in the contextual category, it may be noted that asking the teacher for more clarity about how parts of a task are weighted would allow better allocations of time.

Pintrich's model highlights motivation by articulating it throughout all four phases. Particular emphasis is given to the learner's achievement goal orientation, i.e., whether a learner works to build expertise for its intrinsic value or to develop competence as a commodity that can be traded for social position or other external rewards.

Winne and Hadwin's Model

Winne and Hadwin's (2013) model of SRL has four phases. In phase 1, the learner surveys conditions that might affect work on a task. The model distinguishes internal cognitive conditions from external conditions. Internal conditions include stable motivational factors such as self-efficacy or achievement goal orientation, knowledge and skills that relate to the task at hand, metacognitive knowledge about when and why to apply tactics for learning, and other knowledge of self the learner judges relevant. External task conditions are factors the learner recognizes in the environment that are expected to influence work on the task. Examples include tools available, elements of social context such as whether peers are knowledgeable and willing to help and, importantly, objectives set for the learner. Overall, conditions inform the learner about the context for SRL in subsequent phases.

Based on information assembled in phase 1, in phase 2 the learner sets goals. Some goals concern qualities of cognitive operations that might apply to the task, such as how easy they are to carry out or their history of generating successful results. Product goals concern results at midpoints during the task and on completing it. Goals provide standards for monitoring how well results match intended products, setting a stage for regulation.

Having established goals, the learner completes phase 2 by planning now to accomplish them. Learning tactics are selected and assembled into more complex learning strategies. A learning tactic is an If–Then rule: If conditions of the task at a particular moment have a particular profile, Then apply a particular cognitive operation. For example, if a list of items needs to be recalled in sequence, then invent a serial mnemonic such as ROY G BIV referring to colors of the spectrum ordered by wavelength. Tactics and strategies have qualities such as how easily they can be applied, how predictably they generate expected products and how rapidly they yield products. These standards can be used to monitor cognition 'on the fly.'

Armed with goals and plans, the learner works on the task itself in phase 3. During engagement, learners who are actively SRL frequently metacognitively monitor operations and midpoint products relative to goals set in phase 2. When a discrepancy is detected, metacognitive control is applied to make adjustments.

After a task is completed or, possibly, abandoned, in phase 4 the learner considers whether to make major adaptations in the event tasks like this might arise in the future. Every element of the preceding phases can be a target for regulation. For example, regarding phase 1, a learner may judge more effort needs to be spent surveying conditions or that self-efficacy should be recalibrated.

Winne and Hadwin consider SRL is ubiquitous, not an approach to learning that learners turn off and on. Recursion is a key feature of their model; that is, products generated in any phase can be reinput to that phase to refine is products. Also important is their view that, while phases usually unfold in serial order, learners may retreat or skip a phase.

Zimmerman's Model

Zimmerman's model of SRL derives from a view that "Self-regulated learning strategies are actions and processes directed at acquiring information or skill that involve agency, purpose, and instrumentality perceptions by learners … for students' strategic actions to be described as self-regulated, one must know their academic goals and perceptions of efficacy" (Zimmerman, 1989: 329). Zimmerman's view has roots in Bandura's theory of reciprocal interactions among a person, features of the person's environment and the person's intentional behavior which, in the case of SRL, is to learn. To engage in SRL, Zimmerman stipulates that a learner (1) monitors how

learning is carried out, (2) judges qualities of that engagement or results it produces, and (3) reacts to that judgment when there are differences between standards for engagement and results. Results include inherent motivational and emotional elements. A fourth quality is important. Learners proactively search for opportunities to learn not just subjects they study but also how to improve the process of learning.

SRL events in Zimmerman's model unfold over three serial phases. In a foresight phase, the learner analyzes an assigned or a self-set task. This leads to setting goals and planning how to reach goals in a strategic way. In the foresight phase, the learner generates four key perceptions. One, self-efficacy, concerns the learner's perception of ability to perform actions in the plan. Second, the learner predicts results anticipated by performing those actions. This is an outcome expectation. A third perception concerns the learner's intrinsic interest in or valuing of this outcome. The fourth perception concerns why the learner intends to carry out this task, i.e., a learning goal orientation.

After forethought, in phase 2, the learner begins work on the task itself. Various cognitive processes are applied such as imagery, self-talk, focusing attention, and recalling and applying selected strategies. As processes are enacted, the learner monitors well results correspond to goals. Importantly, Zimmerman notes learners may deviate from plans, experimenting 'on the spot' if a new tack is predicted to improve on the original plan.

In phase 3 of Zimmerman's model, learners reflect on qualities of results actually achieved and make attributions to explain why results turned out as they did. Emotional reactions accompany attributions, as described in Weiner's (2010) theory of motivation.

Zimmerman emphasized that SRL depends on knowledge of how to learn and skill in applying that knowledge. His model also meshes cognitive and metacognitive activities with the learner's motivation, especially as it is shaped by perceptions of self-efficacy and the satisfaction experienced when reflecting on learning activities.

Methodologies and Issues in Researching SRL

An ideal method for researching SRL would generate reliable information about all aspects described by models of it. Also, because SRL is a process unfolding over time, temporal qualities of events and patterns in the succession of events should receive focus. Research has not yet fully surmounted challenges these issues present.

Multiple methods have been used to observe features of SRL. The most common are self-reports, teacher judgments, and traces. Full reviews of these and other methods, and methodological issues associated with them are available in Winne (2010), Winne and Perry (2000) and Winne et al. (2011).

Self-Report Measures of SRL

Self-report methods ask learners to describe their SRL. These are overwhelmingly prevalent in research. Within self-report methods, three main techniques are used: think-aloud protocols, interviews, and inventories.

Think-Aloud Protocols

Think-aloud protocols are grounded in Ericsson and Simon's (1993) research on using verbal reports as data. In a think-aloud protocol, the learner is instructed to talk about what goes on mentally from the moment the task is presented until it is complete or the researcher stops the learner's work. The gist of instructions is, 'Describe everything you can about how you are thinking as you work on the task.' Learners' utterances are recorded and later coded. Counts of and patterns among features of SRL are noted, including goals set, feelings that arise, plans, standards used to monitor, evaluations produced by monitoring, and so on (e.g., see Azevedo et al., 2010).

Interview Protocols

Interviews about SRL can focus on hypothetical but everyday learning tasks or features of SRL that the learner recalls about a task just completed. Information is solicited by guiding questions and follow-ups may be posed if the learner's responses are vague or mention specific features. For example, the Self-Regulated Learning Interview Schedule (SRLIS) developed by Zimmerman and Martinez-Pons (1986) poses a task: "Most students find it necessary to complete some assignments or prepare themselves for class at home. Do you have any particular methods for improving your study at home?" If the learner cannot respond or appears to need prompting, a follow up is offered: "What if you are having difficulty? Is there any particular method you use?" (Zimmerman and Martinez-Pons, 1988: 285). Learners' responses usually are categorized using a preestablished system. Or, responses may be analyzed for emergent themes and features.

Inventories

Because of the relative ease, time saved and simpler scoring that can be realized by administering inventories, they are the most common self-report methods in researching SRL. Inventories typically set a stage for learners to recall SRL events at a relatively coarse grain size, such as 'When you learn…' or 'In this course….' One common inventory is the Learning and Study Strategies Inventory (Weinstein et al., 1987) a standardized, normed 77-item self-report inventory "designed to measure use of learning and study strategies" (Weinstein et al., 1987: 2) by undergraduate students. Example items are statements such as 'I try to interrelate themes in what I am studying' and conditional relations such as 'When work is difficult I either give up or study only the easy parts.' Learners respond using a 5-point scale ranging from 'not at all typical of me' to 'very much typical of me.'

The most common inventory used in research is the Motivated Strategies for Learning Questionnaire (MSLQ; Pintrich et al., 1991). Its 81 items are organized into distinct subscales: intrinsic goal orientation, extrinsic goal orientation, task value, control of learning beliefs, self-efficacy for learning and performance, test anxiety, rehearsal, elaboration, organization, critical thinking, metacognitive self-regulation, time and study environment, effort regulation, peer learning, and help seeking. The MSLQ was designed "to assess college students' motivational orientations and their use of different learning strategies for a college course" (p. 3) regarding actions such as, 'I make good use of my study time for this

course' and conditional relations such as, 'When reading for this course, I make up questions to help focus my reading.' Learners are to 'answer the questions about how you study in this class as accurately as possible' using a 7-point scale anchored by 'not at all true of me: and very true of me.' Instructions and wording of items are often changed slightly to adapt to other situations than the college setting or an entire course.

Methodological Issues about Self-reports

Data generated by self-report methods require the researcher to infer how well a learner's report matches a mental event. The validity of these inferences is challenged by several factors (see Winne and Perry, 2000; Winne et al., 2011). In think-aloud protocols, researchers often find that a learner stops speaking for periods of time while working on a task. Commonly, the researcher prompts the leaner, e.g., 'Please keep speaking.' It is unknown whether SRL events were happening but not reported while the learner was silent.

In think-aloud and interview protocols, it is unknown whether learners are biased to report some kinds of events but not others. The representativeness of a learner's reports is inestimable.

Interview protocols and inventories may introduce information a learner otherwise did not know or would not have considered without the prompts these methods use. If this happens, learners may construct responses consistent with how they believe they might have acted, either because it accords with their view of themselves as a learner or because they judge it socially desirable to have behaved that way. Also, because human memory is constructive, interview and inventory reports may sharpen or dampen features of SRL, or even lead to reporting invented SRL events. How much reports vary from actual SRL is difficult to estimate.

In the case of a think-aloud report, listening to one's oral report about the state of work on a task may trigger metacognitive monitoring that otherwise would not have occurred had the report not be generated. Except for think-aloud reports, the context of SRL events is at least temporally removed from the event per se; or, it may be abstracted in ways that lead to 'average' representations of SRL rather than particular ones. This potential reduction in variance is at odds with a fundamental representation of regulation in SRL as an If–Then–Else rule governed by local and specific conditions that comprise the If element in this representation (Winne, 2010, 2011).

Teacher Ratings of Learner's SRL

Researchers have asked teachers to judge a learner's SRL. Zimmerman and Martinez-Pons' (1988) protocol, the Rating Student Self-Regulated Learning Outcomes: A Teacher Scale, is representative. It asks teachers to rate their students' SRL using 12 of 14 categories on the SRLIS; categories of behavior that usually occur outside the teacher's opportunity to see it, e.g., structuring the environment before starting homework, were omitted. Teachers rate learners using a 5-point scale: 1 = never, 5 = always. Items span learners' usage of a strategy, such as seeking teacher assistance or seeking information. Other items ask teachers to judge observable results of using a strategy, such as whether the assignments were completed on or before due dates and whether the learner set goals and made plans. Teachers' ratings and learners' self-reports on the SRLIS correlated 0.70. However, issues about the validity of inferences regarding learners' self-reports affect interpretations of this correlation, as well.

Traces

Traces are artifacts learners create as they work a task, i.e., traces are accretion data (Webb et al., 1966). Well-designed traces support strong inferences about occurrences of SRL, the context of SRL, and patterns among events that comprise SRL. Suppose a learner is searching the Internet to gather information for a project and is using online software to bookmark Web sites, highlight information within Web sites, develop terms to build a glossary and make notes about information (see Winne and Hadwin, 2013). Suppose in the midst of making a particular note, the learner opens a note made yesterday. A logged record the software makes of this event – a trace – can be interpreted as the learner having metacognitively monitored knowledge while constructing today's note, judging content in a particular note made yesterday would be helpful, and demonstrating motivation to review that information by finding and opening that note, a trace of metacognitive control. Traces of such events interspersed with other kinds of events wherein the learner does not review previous notes while making new ones supports an inference that the learner is self-regulating knowledge construction by metacognitively monitoring information in new notes and exercising metacognitive control to assemble information in old notes with new information. It is logical to infer the learner has a clear outcome expectation and judges there is sufficient incentive to apply that effort.

Traces, particularly when software records them (Winne, 2010), are less susceptible than other methodologies (except full video recording of a learner's work) to challenges in observing SRL. First, context for engaging in SRL can be more fully characterized. Second, a fuller sample of SRL events and their temporal qualities (onset, duration) can be captured without significantly intruding on the task itself. Third, patterns across traces can be investigated to develop more complex accounts of SRL. Fourth, learners' fallible and possibly biased recall of SRL is avoided. A potential important weakness of traces is that, like all data, the researcher must infer what elements of SRL a trace represents. Careful design of traces can lessen but not erase this concern.

Research Findings

Methodological issues affecting SRL research should be remembered in considering findings reported in research involving SRL.

SRL is not always beneficial. Learners sometimes report selecting methods for studying because they are easy to use or to accelerate progress even if they believe other effortful and less rapid methods for studying – the so-called desirable difficulties – would be better for learning (see Bjork et al., 2013). Similarly, procrastination and other self-handicapping techniques, such as when learners report intentionally choosing not to study so they have an excuse for poor performance (see Midgley et al., 1996), are forms of SRL

because learners intentionally decide how to regulate their engagement in (or disengagement from) learning. These decisions, however, depress achievement.

In general, learners' reports of engaging in SRL-related events have moderate positive correlations with academic achievement (e.g., Nota et al., 2004). Supporting or training learners to apply SRL-related actions can improve achievement (e.g., Michalsky, 2013; Sadi and Uyar, 2013) especially when SRL training is part of a multifaceted intervention that provides learners with tactics and strategies for accomplishing academic tasks, such as mathematics (Leidinger and Perels, 2012) and writing (Brunstein and Glaser, 2011).

Correlational and some experimental research suggest several facets that merit attention in fostering learners' use and development of productive SRL. These include designing learning tasks that are complex enough to afford genuine decision making but not so challenging as to lower self-efficacy or overload cognition (Perry, 1998), helping teachers develop beliefs that productive SRL can be supported by directly teaching learners about cognitive tactics and strategies (Dignath-van Ewijk and van der Werf, 2012), designing learning environments that increase learners' intrinsic valuing of school (van der Veen and Peetsma, 2009), and facilitating learners' attention to opportunities to metacognitively monitor and control their learning (Ifenthaler, 2012; Lawanto and Santoso, 2013).

Self-Regulated Learning: Theories, Measures, and Outcomes

Barry J Zimmerman, City University of New York Graduate Center, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Self-regulated learning refers to how students become masters of their own learning processes. Neither a mental ability nor a performance skill, self-regulation is instead the self-directive process through which learners transform their mental abilities into task-related skills in diverse areas of functioning, such as academia, sports, music, and health. This article will define self-regulated learning and describe the intellectual context in which the construct emerged, changes in researchers' emphasis over time as well as current emphases, methodological issues related to the construct, and directions for future research.

Defining Self-Regulated Learning

Self-regulated learning involves metacognitive, motivational, and behavioral processes that are personally initiated to acquire knowledge and skill, such as goal setting, planning, learning strategies, self-reinforcement, self-recording, and self-instruction. A self-regulated learning perspective shifts the focus of educational analyses from students' learning abilities and instructional environments as fixed entities to students' self-initiated processes for improving their methods and environments for learning. This approach views learning as an activity that students do for themselves in a proactive way, rather than as a covert event that happens to them reactively as a result of teaching experiences. Self-regulated learning theory and research is not limited to asocial forms of education, such as discovery learning, self-education through reading, studying, programmed instruction, or computer-assisted instruction, but can include social forms of learning such as modeling, guidance, and feedback from peers, coaches, and teachers. The key issue defining learning as self-regulated is not whether it is socially isolated but rather whether the learner displays personal initiative, perseverance, and adaptive skill in pursuing it.

	Definitions
Self-regulation processes	Self-initiated cognitions or emotions that can affect learning and performance positively or negatively, such as setting effective or ineffective goals.
Self-regulation strategies	Self-initiated methods designed to enhance learning, such as multistep plan to solve story problems in mathematics.
Self-regulation phases	A description of self-regulation processes that are used before, during, and after efforts to learn.
Self-monitoring	Metacognitive tracking of one's self-regulatory processes or outcomes during learning and performance.
Self-efficacy	Involves motivational beliefs regarding personal competence to accomplish a task, such as correcting a sentence for grammatical errors.
Self-regulation of performance	Involves personal efforts to control adverse behaviors and/or emotions during learning, such as impulsivity or anxiety.
Self-regulation events	Measures of self-regulation that are applied during efforts to learn, such as think-aloud protocols or personal logs.

Continued

Most contemporary self-regulation theorists have avoided absolute distinctions between internal and external control of learning and have envisioned self-regulation in broader, more interactive terms. Students can self-regulate their learning not only through covert cognitive means but also through overt behavioral means, such as selecting, modifying, or constructing advantageous personal environments or seeking social support. A learner's sense of self is not limited to individualized forms of learning but includes self-coordinated collective forms of learning in which personal outcomes are achieved through the actions of others, such as family members, teammates, or friends, or through use of physical environment resources, such as tools. Thus, covert self-regulatory processes are viewed as reciprocally interdependent with behavioral, social, and environmental self-regulatory processes.

Self-regulation is defined as a variable process rather than as a personal attribute that is either present or absent. Even the most helpless learners attempt to control their functioning, but the quality and consistency (i.e., quantity) of their processes are low. (Self-regulatory processes are self-initiated cognitions or emotions that can affect learning and performance positively or negatively, such as setting effective or ineffective goals.)

Novice learners rely typically on naive forms of self-regulatory processes, such as setting nonspecific distal goals, using nonstrategic methods, inaccurate forms of self-monitoring (Self-monitoring is metacognitive tracking of one's self-regulatory processes or outcomes during learning and performance.), attributions to uncontrollable sources of causation, and defensive self-reactions. By contrast, expert learners display powerful forms of self-regulatory processes, especially during the initial phase of learning. Students' efforts to self-regulate their learning have been analyzed in terms of three cyclical learning phases. (Self-regulation phases are a description of self-regulation processes that are used before,

during, and after efforts to learn.) Forethought phase processes anticipate efforts to learn and include self-motivational beliefs, such as self-efficacy (Self-efficacy involves motivational beliefs regarding personal competence to accomplish a task, such as correcting a sentence for grammatical errors.), outcome expectations, intrinsic interest, as well as task analysis skills, such as planning, goal setting, and strategy choice. Performance phase processes seek to optimize learning efforts and include use of time management, imagery, self-verbalization, and self-observation processes. Self-reflection phase processes follow efforts to learn and provide understanding of the personal implication of outcomes. They include self-judgment processes, such as self-evaluation and attributions, and self-reactive processes, such as self-satisfaction and adaptive/defensive inferences. Because novice learners fail to use effective forethought processes proactively, such as proximal goal setting and powerful learning strategies, they must rely on reactive processes occurring after learning attempts that often have been unsuccessful. Such unfortunate experiences will trigger negative self-evaluations, self-dissatisfaction, and defensive self-reflections – all of which undermine self-motivation necessary to continue cyclical efforts to learn. By understanding self-regulation in this cyclical interactive way, qualitative as well as quantitative differences in process can be identified for intervention.

Intellectual Context for Self-Regulated Learning Research

Interest in students' self-regulated learning as a formal topic emerged during the 1970s and early 1980s out of general efforts to study human self-control. Promising investigations of children's use of self-regulatory processes like goal setting, self-reinforcement, self-recording, and self-instruction, in such areas of personal control as eating and task completion prompted educational researchers and reformers to consider their use by students during academic learning. Interest in self-regulation of learning was also stimulated by awareness of the limitations of prior efforts to improve achievement that stressed the role of mental ability, social environmental background of students, or qualitative standards of schools. Each of these reform movements viewed students as playing primarily a reactive rather than a proactive role in their own development. In contrast to prior reformers who focused on how educators should adapt instruction to students based on their mental ability, sociocultural background, or achievement of educational standards, self-regulation theorists focused on how students could proactively initiate or substantially supplement experiences designed to educate themselves.

Interest in self-regulation of learning emerged from many theoretical sources during the 1970s and 1980s. For example, operant researchers adapted the principles and technology of Skinner for personal use, especially the use of environmental control, self-recording, and self-reinforcement. Their preference for single-subject research paradigms and time series data was especially useful for individuals seeking greater self-regulation of learning. During this same time period, phenomenological researchers shifted from monolithic, global views of how self-perceptions influenced learning to hierarchical, domain-specific views and began developing new self-concept tests to assess functioning in specific academic domains. The research of Hattie, Marsh, Shavelson, and others was especially influential in gaining new currency for the role of academic domain self-concepts in learning. During this era, social learning researchers, such as Bandura, Schunk, and Zimmerman, shifted their emphasis from modeling to self-regulation and renamed the approach as social cognitive. They identified a new task-specific motive for learning, self-efficacy belief, and they linked it empirically to other social cognitive processes, such as goal setting, self-observation, self-judgment, and self-reaction. During this era, researchers, such as Corno, Gollwitzer, H. Heckhausen, Kuhl, and others, resurrected volitional notions of self-regulation to explain human efforts to pursue courses of learning in the face of competing events. In their view, self-regulatory control of action can be undermined by ruminating, extrinsic focusing, and vacillating which interfere with the formation and implementation of an intention.

Also during the 1970s and 1980s, suppressed writings of Vygotsky were published in English that explained more fully how children's inner speech emerges from social interactions and serves as a source of self-control. Cognitive behaviorists, such as Meichenbaum, developed models of internalization training on the basis of Vygotsky's description of how overt speech becomes self-directive. During this same era, cognitive constructivists shifted their interest from cognitive stages to metacognition and the use of learning strategies to explain self-regulated efforts to learn. The research and theory of Flavell played a major role in effecting this transition by describing self-regulation in terms of metacognitive knowledge, self-monitoring, and control of learning.

Research on self-regulation was also influenced by the emergence of goal theories during the 1970s and 1980s. Locke and Latham showed that setting specific, proximal, challenging but attainable goals greatly influenced the effectiveness of learners' efforts to learn. Theorists such as Ames, Dweck, Maehr, Midgley, and Nicholls identified individual differences in goal orientations that affected students' efforts to learn on their own. These researchers found that learning or mastery goal orientations facilitated persistence and effort during self-directed efforts to learn, whereas performance or ego goal orientations curtailed motivation and achievement. During this same period, another perspective emerged that focused on the role of intrinsic interest in learning. Deci, Harackiewicz, Lepper, Ryan, Vallerand, and others demonstrated that perceptions of personal control, competence, or interest in a task were predictive of intrinsic efforts to learn on one's own. This focus on intrinsic motivation was accompanied by a resurgence of research on the role of various forms of interest in self-directed learning by a host of scholars in North America, Europe, as well as elsewhere, such as Eccles, Hidi, Krapp, Renninger, Schiefele, Wigfield, and others. During these same decades, research on self-regulation of learning was influenced by cybernetic conceptions of how information is processed. Researchers such as Carver, Scheier, and Winne demonstrated the important role of executive processes, such as goal setting and self-monitoring, and feedback control loops in self-directed efforts to learn.

Changes in Emphasis over Time

Before the 1980s, researchers focused on the impact of separate self-regulatory processes, such as goal setting, self-efficacy, self-instruction, volition, strategy learning, and self-management with little consideration for their broader implications regarding student learning of academic subject matter. Interest in the latter topic began to coalesce in the mid-1980s with the publication of journal articles describing various types of self-regulated learning processes, good learning strategy users, self-efficacious learners, and metacognitive engagement, among others. By 1991, a variety of theories and some initial research on self-regulated learning and academic achievement was published in special journal issues and edited textbooks (Zimmerman and Schunk, 2001).

These accounts of academic learning, which described motivational and self-reactive as well as the metacognitive aspects of self-regulation, spurred considerable research. By the mid-1990s, a number of edited texts had been published chronicling the results of this first wave of descriptive research and experimental studies of self-regulated learning. The success of these empirical studies stimulated interest in systematic interventions to students' self-regulated learning and the results of these implementations emerged in journal articles and textbooks by the end of the 1990s.

Emphases in Current Theory and Research

Role of Self-Motivation

There is much current interest in understanding the self-motivational aspects of self-regulation as well as the metacognitive aspects. Self-regulated learners are distinguished by their personal initiative and associated motivational characteristics, such as higher self-efficacy beliefs, mastery learning goal orientations, favorable self-attributions, and intrinsic motivation, as well as by their strategic and self-monitoring competence. The sources of students' self-motivation are of both practical as well as theoretical importance. On the practical side, researchers often confront apathy or helplessness when they seek to improve students' use of self-regulatory processes, and they need viable methods for overcoming this lack of motivation. On the theoretical side, researchers need to understand how motivational beliefs and accompanying affect interact with learning processes in a way that enhances students' initiative and perseverance. A number of self-regulation models have included motivational and learning features as interactive components, such as Pintrich's self-schema model, Boekaert's three-layered model, Kuhl's action–state control model, and Bandura, Schunk, and Zimmerman's cyclical phase model. These models are designed to transcend conceptual barriers between learning and motivational processes and to understand their interaction. For example, causal attributions are not only expected to affect students' persistence and emotional reactions but also adaptations in their methods of learning. Each of these models seeks to explain how learning can become self-motivating and can sustain effort over obstacles and time. The role of motivation in these models of self-regulated learning was compared and contrasted in 2008 in an edited text (Schunk and Zimmerman, 2008). More than 13 sources of motivation were linked to self-regulated learning theoretically and empirically in this research.

Effects of Self-Regulation Training

A second issue that has attracted considerable attention during the last decade is the acquisition of self-regulatory skills in deficient populations of learners. Training programs for these skills have been conducted with diverse populations and age groups of students. These interventions have involved a variety of formats, such as separate strategy or study skill training classes, strategy training linked explicitly to subject matter classes, such as in mathematics or writing, or personal trainer services in classrooms and counseling centers.

One of the most systematic efforts to teach self-regulated learning processes for writing has been undertaken by Harris, Graham, and their colleagues. Their intervention, named the Self-regulated Strategy Development (SRSD) model, was designed to teach various genres of writing skill to learning disabled students who ranged in educational level from elementary to high school. This instructional approach sought to instill self-regulatory processes, such as goal setting, self-monitoring, self-evaluation, self-instruction, self-reinforcement, by using instructional processes such as modeling and fading of cognitive scaffoldings. More than 40 experimental and quasi-experimental studies have been conducted using this model, and a *meta*-analysis revealed that the effect size of SRSD training was large (Graham and Perin, 2007).

A second *meta*-analysis was conducted with 48 training studies of nondisabled primary school children involving regular teachers or experimental trainers (Dignath et al., 2008). Gains were reported in not only academic performance but also in strategic functioning and motivation. The size of the effect of overall self-regulatory training on academic outcomes was medium. However, those studies that provided metacognitive training designed to control, monitor, regulate, and reflect on learning produced a large effect size. Interventions that gave motivational feedback regarding their strategic learning also produced a large effect size, and studies that provided the combination of metacognitive and motivational training strategies yielded a very large effect size. Interestingly, the *meta*-analysis revealed that experimental trainers were more effective than trained teachers in enhancing students' achievement. A subsequent study by Dignath and Büttner (2008) expanded the data base to include secondary school students as well as the primary school students. These researchers found that the overall effect of self-regulatory training on secondary students' achievement was medium in size, albeit slightly smaller than the effect on primary school youngsters. The effect of metacognitive training with secondary students was large, but the effect of motivational training could not be tested due to limited number of studies of secondary students that included this component. These *meta*-analyses established clearly that children as young as primary schoolers profited significantly from self-regulatory training that focused on metacognitive and motivational components of self-regulated learning.

A fourth *meta*-analysis was conducted by Sitzmann and Ely (2011) with 369 self-regulation work-related training studies

involving nondisabled college students or employees who were taught job- or education-relevant knowledge and skills. Sixteen self-regulatory constructs were identified across these studies, and nine of these constructs were significant predictors of students' achievement: goal level, self-efficacy, metacognitive strategies, attention, time management, environmental structuring, motivation, effort, and attributions. The best predictors (i.e., goal level, persistence, effort, and self-efficacy) jointly accounted for 17% of the variance in students' achievement. The effects of self-regulatory training generalized across trainee populations and differences in length of training in these studies. The researchers recommended future research that does not depend on self-reported data but instead involves measures that can capture the dynamic nature of self-regulated learning.

Methodological Issues

Initial efforts to measure self-regulated learning processes relied on inventories in which students are asked to rate their use of specific learning strategies, various types of academic beliefs and attitudes, typical methods of study, as well as their efforts to plan and manage their study time. Another method was the use of structured interviews that involved open-ended questions about problematic learning contexts, such as writing a difficult essay, completing math assignments, and motivating oneself to study under challenging circumstances. The latter form of assessment requires students to create their own answers and requires trained coders to recognize and classify various qualitative forms of self-regulatory strategies. (Self-regulatory strategies are self-initiated methods designed to enhance learning, such as multistep plan to solve story problems in mathematics.) Although both of these approaches have reported substantial correlations with measures of academic success, they are limited by their retrospective or prospective nature. As such, they depend on recall or anticipatory knowledge rather than on actual functioning under taxing circumstances.

To avoid these limitations, recent research efforts have focused on studying self-regulation during actual learning 'events' using measures such as trace logs, think-aloud protocols, direct observations, structured diaries, and microanalysis (Zimmerman and Schunk, 2011). Trace logs refer to environmental indicators of cognition, such as computer records of requests for information when learning online. Think-aloud protocols involve recordings of students' verbalizations of their thoughts and cognitive processes while learning, such as self-directed comments about changes in strategies. Direct observations pertain to records of students' actions and comments gathered by trained coders, such as the frequency of requests for help. Structured diaries refer to prescribed records that are completed by the learner themselves, such as the quality and quantity of their studying. Microanalysis focuses on answers to specific questions that are posed to assess well-established self-regulatory processes and motivational beliefs or feelings at key points before, during, and after feedback cycles. These event measures seek to provide a window on students' self-regulatory actions and reactions as they occur in real time and dynamic environmental settings.

There is recent evidence that event measures of self-regulatory processes derived from structured diaries can surpass the validity of summary measures obtained from interviews (Nandagopal and Ericsson, 2011). Diary measures were more predictive than interview measures of differences in self-regulation processes between high-, average-, and low-achieving upper division college students majoring in science. More specifically, these researchers discovered that shifts in the timing and the adaptation of self-regulatory processes by these advanced students to varying class requirements (e.g., reading vs test preparation) were more predictive of their achievement than their overall use of these processes. However, there is other research (Winne and Jamieson-Noel, 2002) indicating that even when diary measures focused on detailed learning events, the calibration of these self-reported measures with traces of the students' actual behavior could be a problem. Clearly further research is needed that employs diverse methodologies for assessing self-regulated learning events. (Self-regulation events are measures of self-regulation that are applied during efforts to learn, such as think-aloud protocols or personal logs.)

Future Directions for Research and Theory

Role of Computer Technology

The computer has been widely embraced as an ideal instrument to study and enhance students' self-regulation of learning. Software program menus can be faded when they are no longer needed and students' performance processes and outcomes can be logged in either hidden or overt files. Computers can provide invaluable feedback to the experimenter or the learner because performance outcomes can be stored, analyzed, and graphed in countless ways to uncover underlying deficiencies. Three notable efforts to employ computer technology to study self-regulation of students' learning have emerged to date.

Winne has developed a specially designed computer environment to assess and facilitate self-regulation by students during studying. This software, which is labeled gStudy, provides learners with self-regulatory tools, such as note-taking, that can be used to study different topics. For example, an assigned reading for a history course can be downloaded into gStudy, and as the student reads the text, key passages can be highlighted, cut and pasted to a separate text file, table, or diagram. The software also provides a menu of templates for diagramming or organizing the notes. The purpose of gStudy is to teach students how to 'bootstrap' higher levels of self-regulation during studying.

Azevedo and his associates have cautioned that learning in contemporary hypermedia settings is especially challenging to educators because it is nonlinear, multirepresentational, and open-ended. To learn effectively in these environments, students need to use self-regulatory processes, such as planning, knowledge activation, metacognitive monitoring, and reflection. To implement these processes, the researchers developed MetaTutor, a hypermedia environment designed to model, trace, and foster students' self-regulation of learning. Toassess the effectiveness of MetaTutor training, the investigators have developed think-aloud protocols that can be related to computer traces (e.g., accessing specific hyperlinks) as well as to electronic measures of science achievement.

Anastasia Kitsantas and Nada Dabbagh (2010) published a teacher's manual for teaching self-regulation via supportive computer learning technologies, such as Skype, Weblogs, Wikis, Facebook, and blackboard. Six self-regulatory processes were taught: goal setting, task strategies, self-monitoring and self-evaluation, time management, and help seeking. A four-level sequential training model was employed involving observation, emulation, self-control, and self-regulation. For example, goal setting was taught initially through modeling and emulation before it was practiced and adapted to the students' learning context. Although research has been supportive of the effectiveness of these computerized efforts, *meta*-analytic studies of their relative effects are needed.

Role of Teachers

There is growing research that teachers play an important role in children's self-regulation during class as well as with homework. *Meta*-analytic research (Dignath et al., 2008) has revealed regular teachers were less effective than experimental trainers in conveying self-regulated learning processes. However, there is evidence (Stoeger and Zigler, 2008) that regular school teachers could be trained to convey self-regulated learning skills to fourth graders as part of their regular mathematics assignments during an intensive 5-week intervention. In research conducted with older at-risk students enrolled in basic mathematics courses at a technical college, instructors who were trained to provide self-regulatory instruction produced significant results (Zimmerman et al., 2011). Compared to students of untrained instructors, students who received self-regulatory training displayed more accurate self-judgments and higher achievement on periodic exams during the semester and on a final departmental exam. Clearly, teachers can be trained to convey self-regulated learning processes to students ranging from elementary to collegiate level, but research on long-term effects of such instruction is limited to date. This issue is in need of further research.

Out-of-School Influences

There is well-established research showing that out-of-school factors such as peer groups, families, and part-time employment strongly affect school, but there is only limited evidence to date that these social groups have a significant influence on students' self-regulatory development. However, Brody and his colleagues found that parental monitoring and setting standards regarding their children's performance was very predictive of the children's academic as well as behavior self-regulation, which in turn was predictive of their cognitive and social development. Another study of parental processes by Martinez-Pons found that parental modeling and support for their children's self-regulation was predictive of the youngsters' success in school. There is additional research regarding the psychosocial origins of self-regulatory competence in academic learning.

Grolnick and her colleagues have studied the effects of parental autonomy support and involvement on their children's sources of motivation, such as perceived competence, control understanding, and self-regulation beliefs. Autonomy support refers to parents' valuing and supporting their children's initiation and problem solving activities. These researchers reported the results of several correlational studies indicating a significant predictive path from parental processes to their children's achievement via their children's motivational beliefs. These researchers advanced the hypothesis that children's self-regulatory motives are developed by their parents before they enter school and continue to be supported afterward. A 3-year longitudinal study of parental involvement was conducted with third, fourth, and fifth grade elementary school students. It was found that parents that increased their involvement over time had children who increased in personal competence motivation, increased reading and math grades, and decreased their learning problems over time. Clearly there is a growing body of research regarding the important role of parents on children's self-regulation of learning, but future research is needed on the impact of peers, especially classmates, on students' self-regulation of their learning.

Self-Regulated Learning versus Self-Regulation of Performance Processes

A final issue requiring further research involves the distinction between self-regulation of learning processes and self-regulation of performance (Self-regulation of performance involves personal efforts to control adverse behaviors and/or emotions during learning, such as impulsivity or anxiety.) processes. The former construct refers to personal efforts to acquire advantageous knowledge and skill, such as proficiency in writing or sport. The latter construct refers to personal efforts to control adverse behaviors, such as impulsivity, failures in volition, and the inability to control emotions or addictions. The latter deficiencies in performance have been attributed to a lack of self-control or self-discipline and have been the focus of study by developmental and clinical researchers.

These behaviors have been defined operationally as 'self-controlled' when they are diminished through conscious effort, such as delay of gratification and relapse prevention. Although the context differs between learning settings (acquiring positive behaviors) and performance settings (avoiding negative ones), there is no inherent reason why measures of self-control should not be predictive of students' academic achievement. There is research (Duckworth and Seligman, 2005) indicating that students' self-discipline measures are significant predictors of students' academic achievement, but there is also evidence that self-regulated learning measures may predict better (Zimmerman and Kitsantas, 2014). Future research needs to address the relation between learning and performance measures of self-regulation.

Conclusion

After more than three decades of research, self-regulated learning has emerged as a widely studied construct assessing self-initiated and self-sustained efforts to acquire metacognitive knowledge and task-related skill. At the outset, self-regulation researchers focused on separate processes such as goal setting, but successful findings led them to consider the interaction of these processes with others in more complete models. In addition to metacognitive processes, integrative models

included self-motivational processes. Various integrative self-regulatory models were compared in a series of edited books and journal articles, which attracted the attention of educators seeking to enhance their students' proactivity in academic and nonacademic areas of functioning. The effectiveness of these interventions has been assessed primarily with questionnaires and interviews, and several *meta*-analyses of theses interventions have reported encouraging results. However, important questions remain to be answered regarding real time measures of self-regulatory processes, and new methodologies have emerged that can capture and explain this dynamic data in greater detail.

Abstract

Self-regulation is a topic of enormous theoretical and empirical interest to developmental scientists, as evidenced by the number of articles, review chapters, and books or monographs pertinent to self-regulatory processes that have appeared in the literature in recent years. Self-regulation refers to the rules or laws governing individual conduct (the functioning of the self) and is understood to pertain to the individual's engagement with his or her ecology or context. Self-regulation processes include the cognitive, emotional, and behavioral facets of the individual; involve both organismic (physiological) and intentional functioning; reflect both fluid and crystallized individual attributes; and are the personological component of the mutually influential relations between the individual and the context (represented as individual ↔ context relations, or what Brandtstädter terms 'developmental regulations'). Accordingly, self-regulation constitutes the fundamental process of human development and encompasses much more than other self-governance constructs, such as self-control, grit, soft skills, or noncognitive skills. As such, self-regulation constitutes a process with both basic adaptive significance and important implications for human health.

The regulation by individuals of their relationship with their complex and changing physical, social, cultural, and historical context is the key problem for successful development across life (Baltes et al., 2006). Arguably, the understanding of the system involved in linking individuals and contexts becomes the essential intellectual challenge for developmental science.

Indeed, Posner and Rothbart (2000) have stated that "understanding self-regulation is the single most crucial goal for advancing an understanding of development" (p. 427). Accordingly, to (1) understand development, especially as conceived of within a relational developmental systems perspective (Overton and Mueller, 2012) that focuses on the mutually influential relations between individuals and contexts, or individual ↔ context relations (Brandtstädter, 1998) and, centrally, to (2) appreciate the role of a person's own contributions to this development, focus should be placed on the role of an individual's actions in regulating the course of engagement with the context and in fostering constancy and change (in actualizing plasticity) across life. Self-regulation is, then, a fundamental focus of developmental science across the life span. The features of developmental regulation may be especially salient for adaptation at times of individual or ecological transition. Given the transitions of the adolescent period, this time of life is especially important for maintaining or furthering self-regulations that enhance adaptive functioning. In addition, it represents a naturally occurring ontogenetic laboratory in which to study the structure and function of self-regulation processes.

Across their ontogeny, humans actualize a rich potential for cognitive and behavioral plasticity (Lerner, 1984). The evolutionary gains in complexity (anagenesis) that underlie human plasticity have come at a price, however, that is, neotenous development (Gould, 1977). In other words, the development of humans' eventually high-level cognitive and behavioral capacities is ontogenetically protracted. Other organisms, whose nervous systems have low ratios of association-to-sensory fibers (A/S ratios; Hebb, 1949), are more stereotyped in their eventual, final level of ontogenetic functioning (Schneirla, 1957). That is, stimulus input is highly correlated with behavioral output. These organisms are adapted to ecological niches in which they can survive and reproduce despite the fact that their behavior is regulated strictly by their context. Their relatively low level of ontogenetic plasticity (and their low A/S ratio) solves the problem of the regulation of organism – context relations and thus of adaptation (Hebb, 1949; Schneirla, 1957).

For humans, however, the situation is quite different. The complexity of their nervous systems and the multiple levels of their contexts mean that there is not necessarily one adaptive relation between context and behavior; which behaviors are requisite for adaptation are uncertain. As a consequence, although plasticity affords vast variation in behavior, the evolutionary status of humans means that the selection of adaptive options from within the array of behaviors available to them constitutes the key challenge in human development. As such, self-regulation pertains to all aspects of adaptation, as individuals alter their behaviors – as well as thoughts, attention, and emotions – to react to different contexts and modulate their reactions to and actions aimed at influencing their contexts (Shonkoff and Phillips, 2000). Accordingly, self-regulation involves multiple levels of functioning, ranging from physiological functions to complicated, intentional thought processes to organismically based or purposeful actions. The latter actions may be designed to either enact strategies to attain the aims of or goals for selected transactions with their context or to compensate effectively when goals are blocked or initial actions fail (Baltes et al., 2006; Geldhof et al., 2010; Gestsdottir and Lerner, 2008; McClelland et al., 2010). Self-regulation, then, may be defined as "the ability to flexibly activate, monitor, inhibit,

* This work was supported in part by grants from the John Templeton Foundation.

persevere and/or adapt one's behavior, attention, emotions and cognitive strategies in response to direction from internal cues, environmental stimuli and feedback from others, in an attempt to attain personally-relevant goals" (Moilanen, 2007, p. 835).

Self-Regulation in Adolescence

Across the life span, individuals live in complex physical, social, cultural, and historical contexts. To thrive, individuals make decisions about how to act in ways that meet personal needs and environmental demands (Brandtstädter, 1998). In other words, to be adaptive, individuals must act in ways that support their own healthy functioning and are of benefit to their context. Arguably, these requirements for adaptation undergo significant developmental change during the second decade of life, and changes during these years can set the course for future development (Gestsdottir and Lerner, 2008).

During adolescence, individuals need to accomplish several adaptive tasks involving self and context. First, they must establish and then build knowledge about the requirements for personal adjustment, given their particular characteristics of physiological, physical, psychological, and behavioral individuality. They also must learn the demands for adaptation present in their specific ecological niche. Second, during this portion of life, a foundation needs to be established, and then enhanced, to attain the cognitive and behavioral skills needed to set the goals necessary for survival and, even more, for thriving. Thriving involves taking actions that optimize one's chances for a life marked by health and positive exchanges with one's world (Lerner et al., 2001).

To accomplish these ends, the developing abilities for strategic thinking and executive functioning need to be coupled with the actions required for turning life goals into reality, that is, into successful personal adjustment and ecological adaptation (Baltes et al., 2006). These adaptive tasks are especially complicated during adolescence. Developing links between thinking and action in the service of adaptation occurs during adolescence in the midst of emerging and, in many cases, rapidly changing developmental trajectories. For instance, such trajectories involve changing neurological, cognitive, emotional, somatic, and behavioral characteristics that evolve in relation to normative and often nonnormative changes in key life contexts (e.g., families, peer groups, schools, and communities).

The goal of engaging in these adolescent adaptive tasks is optimizing one's developmental trajectory. When one is moving toward an end state or goal that is uncertain, how does one select the best means to get there? This question reflects the fundamental adaptive challenge of the first two decades of life (Geldhof et al., 2010; Gestsdottir and Lerner, 2008).

How might adolescents meet this challenge? As is the case for people at all points across the life span, adolescents are influenced by their environments and, in addition, they simultaneously select, create, and change these settings (Lerner, 1982). This bidirectional, or reciprocal, relation between individual and context creates 'circular functions' (Schneirla, 1957) in ontogeny and, through such relations, individuals become shapers of the contexts influencing them. Thus, individuals become producers of their own development (Lerner, 1982). Accordingly, during adolescence, individuals are active agents in their *developmental regulations* – that is, they are active agents in mutually influential relationships among the organizational levels within a dynamic, developmental system. These relationships involve variables from integrated biological through historical (temporal) levels. These integrated interlevel relations may be represented as Level 1 ↔ Level 2 and, when focused on the developing individual and his or her active, changing context, these developmental regulations may be represented as individual ↔ context relations.

When these mutually influential relations are beneficial for both the person and his or her context, they may be termed *adaptive* developmental regulations (Brandtstädter, 1998). Given the foundational and developmental knowledge acquisition and skill attainment required for thriving during adolescence, however, and the embeddedness of these requirements in multiple and complex trajectories across the developmental system, the challenges to manifest adaptive developmental regulations are enormous (and arguably ontogenetically distinct) during the adolescent portion of the life span.

Organismic and Intentional Self-Regulation

In the last 10–15 years, the theoretical focus on self-regulation has been coupled with burgeoning research about the ways in which the developing physiological, psychological, and behavioral attributes of adolescents coalesce to provide the means for these attributes to actively contribute to mutually beneficial relations with their contexts. The attributes through which the individual contributes to these developmental regulations may be termed *self-regulation*.

Clearly, our conception of self-regulation encompasses two integrated but nevertheless distinguishable processes. As noted, these processes involve either primarily physiological (or organismic) processes as well as primarily intentional processes. Gestsdottir and Lerner (2008) have explained that *intentional self-regulations* (ISRs) are contextualized actions that are aimed actively toward harmonizing demands and resources in the context of personal goals to attain better functioning and to enhance self-development. ISR is characterized by goal-directed behaviors. ISR processes are more readily available to consciousness than processes and structures of *organismic regulation*, which are broad, ontogenetically consistent (i.e., relatively continuous) attributes of a person that involve biologically based, physiological structures, and functions that contribute to the relationship an individual has with the environment. Such organismic characteristics (e.g., hypothalamic control of body temperature, circadian rhythms, pubertal timing, and temperamental attributes, such as threshold of responsivity or quality of mood) are under no or limited control of the person, and they do not involve intentional efforts of the person to regulate his or her individual ↔ context exchanges.

Both organismic and ISR processes must be integrated across adolescence for adaptive developmental regulations to exist and for the developing person to thrive, not only during the second decade of life but also across the transition into and throughout the adult years. To date, however, such an integrated and life-span approach to self-regulation during adolescence has not been fully formulated. Such an integrative

approach would require scholarship about each of the two domains of self-regulation processes as well as about their systematic interrelation within and beyond adolescence.

ISR in Adolescence

Brandtstädter (1998) has noted that a major difference between infancy and early childhood and later developmental periods – for instance, adolescence – is that the intentional actions of young children do not involve an intention to promote their development. This notion of a personal future and the intentional actions that result from such a conception begin to formulate in adolescence. Brandtstädter (1998) has explained that

"[d]uring the transition to adolescence…the individual's conceptions of self and of personal future become articulated enough to guide intentional activity. External…demands originating in the familial and larger social context become increasingly internalized and integrated into process of self regulation and self-evaluation; with the progression from a…external mode of developmental control to an increasingly intentional and autonomous mode of intentional self-development, a new and higher level in the regulation of ontogeny is reached. This reflexive-intentional mode has been given rather short shrift in developmental research" (pp. 826–827).

Moilanen (2007) made a similar argument when she differentiated between short-term self-regulation and long-term self-regulation, which she believes to be characteristic of adolescence and to represent a developmental shift in functioning. To exhibit long-term self-regulation, the young person must control impulses and direct effort over longer periods of time. This effort may involve substantial planning and, for the most part, is acquired in adolescence (Moilanen, 2007).

ISR requires the adaptive application of fluid regulatory abilities as well as the knowledge and application of crystallized self-regulation skills. Fluid self-regulatory abilities represent highly cognitive processes that emphasize growth during the first part of the life span and subsequent declines throughout adulthood and old age. Components of fluid self-regulation have been summarized as executive function and include, but are not limited to, working memory, cognitive disengagement, sustained attention, and cognitive inhibition. Crystallized self-regulatory skills represent experiential shaping of the cognitive affective processing system as discussed by Mischel (Mischel et al., 1972) and others (e.g., Geldhof et al., 2010). Crystallized components of self-regulation include, for instance, expectancy, value beliefs, and action-control beliefs.

Accordingly, ISR is a construct that includes other self-governance constructs, such as soft skills, self-control, delay of gratification, or grit. These latter constructs tend to be conceptualized and measured either in laboratory situations (e.g., delay of gratification) or in regard to situation-specific reactions to distracting or off-task stimulation (e.g., delay of gratification, self-control), to pertain to a narrow band of self-governance behaviors (e.g., persistence in the face of blocked behaviors, grit), or to constitute mislabeled or incorrectly conceptualized self-governance processes (e.g., labeling the crystallized and fluid cognitive skills involved in goal management and executive functioning as noncognitive skills is a misnomer). In turn, ISR involves (1) selecting and managing positive and important life goals; (2) using strategies to obtain the resources, or engaging in the executive functions, required to optimize one's chances of reaching selected goals (and here, self-control or delay of gratification may be some of the strategies used for optimization); and (3) having the ability to compensate effectively in the face of failure or of a blocked or lost goal (e.g., making a new goal selection in the face of loss may be a useful compensation behavior).

Considerable theoretical burden then is placed on ISR in constituting the individual component of the adaptive relationship between the individual and the context (i.e., adaptive individual ↔ context relations) requisite for both individual thriving and a positive social world. It may be that ISR does more than just enable the individual to draw from and contribute positively to the context that is supporting the positive development of the individual.

Features of Intentional Self-Regulation in Adolescence

Gestsdottir and Lerner (2008) and Gestsdottir et al. (2011) have reviewed the burgeoning literature describing the structural and functional changes in ISR across adolescence. Much of this research has used the selection (S), optimization (O), and compensation (C) (or SOC) model. Baltes, Baltes, and colleagues (e.g., Baltes et al., 2006; Freund and Baltes, 2002) developed a measure to conceptualize and index, respectively, ISR. To illustrate the features of ISR in adolescence, and to point to the impact of ISR on adaptive developmental regulations during this period, it is useful to focus on the data pertinent to the SOC model.

As presented in Gestsdottir et al. (2011), SOC scores covary positively with positive youth development (PYD) and negatively with problem behaviors. This work also identified the structure of SOC over the adolescent period. Using data from the longitudinal 4-H Study of PYD (J. Lerner et al., 2012), an assessment in early adolescence (in grades 5, 6, and 7, approximately ages 10–12 years) found that SOC scores were best represented through a global structure rather than through three differentiated processes. By grade 8, however, evidence increased for a more tripartite-like structure of elective selection (ES), optimization, and compensation. By grade 10, the presence of a four-component structure of ISR can be confirmed: ES, optimization (O), compensation (C), and loss-based selection (LBS). Even though the SOC processes are not fully differentiated or developed, even by grade 10, in each study, SOC scores correlated positively with indicators of PYD and negatively with substance use, delinquency, and depressive symptoms.

Furthermore, within and across time (i.e., at all grades) Gestsdottir et al. (2011) noted that links between SOC scores and indicators of positive development and problem behaviors were all in expected directions. Moreover, the relationship among scores for the SOC processes and for developmental outcomes (positive development, drug abuse, delinquency, and depression) was strongest for the optimization and

compensation components. In addition, SOC scores were more strongly related to indicators of positive development than to problematic behaviors, which is consistent with the idea that SOC skills contribute to successful life management – that is, to the selection and attainment of goals that can further healthy development.

Urban et al. (2010) indicated that the 4-H Study data set also was used to examine possible links between self-regulatory processes and characteristics of the ecology in which the person is embedded. For instance, analyses employing data from grades 5 to 7 illustrated the complex interplay between individual and context that may underlie the adaptive developmental regulations promoting positive development. Exploring whether the ISR ability of youth interacted with participation in out-of-school time (OST) activities in predicting PYD among adolescents living in neighborhoods with relatively low levels of ecological assets, 4-H Study-based research found that youth in these settings who had the greatest capacity to self-regulate (i.e., youth with the highest SOC scores) benefited the most from involvement in OST activities. The strength of these relationships was particularly the case for girls, however. For boys, there were fewer significant relationships found among self-regulation, OST activity involvement, and either PYD scores or scores for depression and risk behaviors (Urban et al., 2010).

In turn, Bowers et al. (2011) examined the development of ISR across seven years of adolescence (grades 5–11) to ascertain whether distinctive patterns of ISR development existed, whether these trajectories differed in relation to several grade 5 parenting characteristics, and whether ISR trajectories were linked to positive and negative developmental outcomes at grade 11. The results indicated that across the developmental period spanning grade 5 to grade 11, the majority of youth in the sample experienced a steady decline in global SOC. By the fourth wave of data collection (grade 8 or approximately 14 years of age), a subset of youth experienced a marked decrease in reported global SOC, whereas another group reported an increase in global SOC. A fourth trajectory group initially reported very low global SOC across the early grades but reported near-average SOC in later grades. Overall, group comparisons indicated that the elevated SOC and steady-decline groups reported higher levels of parental warmth, monitoring, and school involvement at grade 5, as well as higher levels of PYD and contribution at grade 11. In comparison, the late-onset group had significantly lower levels of all three parenting measures at grade 5 than the steady-decline and elevated groups, but they did not differ from these two groups in outcomes at grade 11. The reverse was true for the pronounced-decline group. Although not significantly different in the measures of parenting at grade 5, the pronounced decline group was marked by lower levels of PYD and contribution at grade 11.

Future Directions

On the basis of our review of the literature on ISR in adolescence, future research should focus on the relationships among ISR, ecological assets, and thriving in adolescence. In particular, research should take a systematic approach to the study of the longitudinal, bidirectional relationships among individual strengths and contextual assets. These nuanced analyses should seek to ascertain the presence and bases of interindividual differences in the system of relationships among ISR, ecological assets, thriving, and risk and problem behaviors. Several of the studies we have discussed point to sex differences, which should be examined further.

In addition, the 4-H Study sample (which most of the studies reviewed used) does not include representative samples of racially and socioeconomically diverse youth. As such, an important direction for future research will be to study the role of ISR in thriving among adolescents who vary in age, race, socioeconomic status, religion, and a host of other demographic categories (e.g., immigrant status, single- vs. two-parent households) as well as sex. These demographic categories are potential markers of variation in the availability of ecological developmental assets in the lives of youth. As such, future research should begin to build a knowledge base to answer questions about what assets, for youth with which characteristics or backgrounds, are linked to PYD in the face of particular facets of ISR (e.g., the SOC processes of ES, O, C, or LBS).

When asking such questions, the phrase 'characteristics or backgrounds' should be understood to include features of organismic self-regulation – for instance, temperament attributes, pubertal characteristics, or sleep–wake cycles (circadian rhythms) – of particular salience in understanding individual differences among adolescents (Gestsdottir and Lerner, 2008). In other words, a key direction for future research about the impact of ISR processes during adolescence is to consider the interactions among attributes of both the organismic and the intentional facets of the self-regulation process.

Future research would profit by considering the relationship between SOC and thriving across a range of environments – for example, resource-restricted vs. resource-abundant settings or normative environments vs. settings that have been beset by either natural disasters (floods, earth quakes, or hurricanes) or human-made calamities (e.g., wars). In addition to exploring a range of environments, it would be fruitful to explore how an individual's SOC scores relate to those of their peers. For example, do youth with relatively lower SOC scores exhibit higher levels of thriving if their closest peers score high on measures of self-regulation? Does the self-regulation of one's peers serve as a protective factor for youth? This focus will allow researchers to extend these questions to a range of contextual settings not yet considered in ISR research, either in adolescence or across other portions of the life span.

In addition to issues of sampling of people and settings, the study of ISR would gain from other methodological innovations. The 4-H Study of PYD has assessed ISR using the SOC questionnaire. Although the data derived from the 4-H study attest to the psychometric quality of the measure, particularly in regard to evidence for its concurrent and predictive validity, problems of method variance accounting for some of the findings cannot be eliminated unless questionnaire findings are triangulated with results derived from the use of other types of measures (e.g., data associated with ecological or experimental observations, interviews, or expert ratings).

Use of multiple methods to assess ISR processes may enable more differentiated knowledge about the structure and function of these processes. For instance, in regard to the functions

of the four SOC structures (ES, LBS, O, and C), theory specifies that successful development encompasses the coordinated integration on selection, optimization, and compensation (Freund and Baltes, 2002; Marsiske Lang et al., 1995). For instance, optimization efforts most likely lead to higher levels of functioning only when they are focused on a delineated number of domains of functioning instead of being diffused among many domains. Similarly, selection per se does not ensure high achievement if no goal-relevant means are applied (e.g., wanting to have high peer status but using no means – athletic, social, or academic – to attain that status will not make someone popular). Finally, the adaptiveness of compensation needs to be seen in the context of the entire goal-system (e.g., "How many other goals are there that need resources for optimization?" or "How important, relative to other goals, is a threatened goal?") and the availability of resources. It does not appear to be adaptive to put a lot of one's resources into a relatively unimportant domain of functioning at the cost of having to neglect more important goals (Freund et al., 1999).

The conceptualization of ISR as the coordinated integration of selection, optimization, and compensation implies that these interactions share attributes. Few studies, however, have examined whether selection, optimization, and compensation interact in the prediction of adolescent outcomes. Instead, a summative SOC score often is used in such prediction analyses (e.g., Zimmerman et al., 2007) or the subscales are entered without considering interactions (Gestsdottir et al., 2009). Therefore, it is important that future research systematically test for the presence of such interactions.

In the conduct of such tests, a more accurate and comprehensive picture will be obtained of the ways in which ISR behaviors are linked to adolescent development outcomes. In addition, disaggregating and assessing the interactions among SOC scores would allow researchers to create SOC profiles (e.g., one could use configural frequency analysis to test whether certain profiles of selection, optimization, and compensation behaviors characterize youth from different contexts and whether these profiles are related to outcomes (von Eye et al., 2010)). Furthermore, such disaggregation would allow for the examination of interactions among individual SOC behaviors and contexts.

In the 4-H Study reports reviewed earlier, selection was not related to any outcomes when controlling for optimization and compensation (which, in turn, were both strongly related to youth outcomes). This lack of relationship could be the result of having omitted the assessment of interactions among selection and contextual factors. Some 4-H Study data suggest that such assessments would be valuable. Napolitano (2010) studied 4-H Study youth during grade 8. He found that selection was important for some of these youth – that is, selection was important for individuals living in settings with low levels of ecological assets. Napolitano suggested that youth living in these settings have relatively few viable options for gaining thriving-related resources and, as such, selection of these resources would be of great benefit. In turn, however, in settings with relatively high levels of ecological assets, youth have many different options for attaining positive development-related goals and, as such, selection may not be as salient. These ideas are provocative and are consistent with the findings of Urban et al. (2010). Both the Urban et al. (2010) and the Napolitano (2010) findings point, then, to the usefulness of more studies that assess how different components of ISR processes may, within differentiated sectors of the context, interact in the promotion of thriving.

If processes of ISR are to fully meet the theoretical burden placed on them in regard to linking with ecological developmental assets in the promotion of thriving in adolescence, then research needs to move beyond observing the role of ISR processes within descriptive, longitudinal studies. Theory-predicated, intervention research (e.g., involving randomized control trials) is needed to assess whether enhancement of the abilities of youth to intentionally regulate their own behaviors can result in improvements in their goal selection, pursuit, and management skills and, ultimately, their characteristics of positive development. Given the consistency of support for the role of SOC processes in thriving that has been derived from the 4-H Study data set and, more generally, the evidence associated with developmental systems theories-related research about the plasticity, the potential for systematic change, that characterizes adolescent development (J. Lerner et al., 2009), optimism is warranted that successful community-based intervention programs seeking to promote gains in SOC skills can be implemented. Indeed, Lerner (2004) has noted that effective youth development programs are marked in part by the inculcation through effective mentoring of the sorts of selection, optimization, and compensation skills involved in the SOC model of ISR. The success of such programs in fostering the growth of SOC-related skills suggests that it is reasonable to launch intervention efforts to enhance thriving through mentoring that is aimed at elevating the ISR skills of diverse youth.

To test the potential effectiveness of such interventions, additional simulation-based studies may be warranted. Systems science-based methodologies, such as system dynamics, can be utilized to test the relative contribution of individual self-regulatory abilities and ecological assets to the thriving of youth. These systems-based methodologies can be used to test potential policy levers and may aid in decision making regarding the investment of resources in elevating individual's self-regulation skills and enhancing the availability of resources in community settings (Urban et al., 2011).

Conclusions

If future research is marked by these methodological and substantive innovations, then developmental scientists will be able to gain an important, new understanding of how individuals may play a positive, productive role in their own development. Such knowledge will enable scientists to contribute to a key applied implication of all approaches to PYD (J. Lerner et al., 2009). That is, by enhancing the positive connections between diverse youth and their contexts, all young people can be put on a more positive pathway across their adolescent years.

Abstract

Self-regulation is a construct that represents the development of children's abilities to follow the everyday norms and practices that are embraced by their caregivers, teachers, peers, and cultures. It is a complex and highly individualized ability that relies on multiple physiological, psychoneurobiological, and cognitive processes and is shaped by socialization and caretaker instruction. This article provides a general overview of the social history and mechanisms underlying self-regulation.

Historical and Clinical Contexts

Self-regulation is a construct that represents the development of children's abilities to follow the everyday norms and practices that are embraced by their caregivers, teachers, peers, and cultures. Self-regulation is an intrinsic part of the socialization process, especially during the formative early years of life. Most children develop self-regulation abilities by the time they are 5 years old. While young children initially have trouble with self-inhibition, they strengthen these skills while simultaneously developing control over facial and emotional expressions (Carlson, 2005). Children who do not develop these skills at a young age are at higher risk for developing behavioral disorders later in life. Although a majority of children are able to self-regulate as young as 2–3 years old, some children begin to exhibit dysregulated behaviors instead. These behaviors vary across cultures but may include resistance to requests made by adults, difficulty with routines, high levels of activity, and unfocused attention often associated with an inability 'to wait' or a poor temperament. The early emergence of dysregulated behaviors appear to act as a predecessor to the development of mental health issues later in life.

Perhaps for this reason, the modern movement of research aiming to understand self-regulation began in the late twentieth century as clinical investigations. Previous findings, primarily from North America and Western Europe, on topics such as impulse control and resistance to discipline implicated factors such as 'ineffective parenting,' as well as distortions in the child's own cognitive or language skills. With rare exceptions, few attempts were made at the time to understand antecedents, culture- or age-related correlates, and consequences of early self-regulated or dysregulated behaviors. However, as a more authoritarian and less authoritative parenting style began to emerge at the turn of the century, a more comprehensive and integrative perspective was assumed to broaden the developmental model and provide insights about multiple contributors to problematic behaviors. Family and social standards were increasingly emphasized because of their relevance for self-regulation. These studies focused on the characteristics and consequences of authoritative parenting, children's autonomy needs, and understanding how the self-determined needs of the individual balance with the value based requirements of social–cultural groups. Such concerns formed the foundation of early self-regulation research.

Most recently, advances in physiological, cognitive, and brain-based methods have shifted this research toward an examination of multileveled explanations describing mechanisms of compliance and self-regulation. Meanwhile, the increasing cultural diversity in the populations of many of the countries prominently represented in research seem to have raised awareness of the role-differing cultural norms as well as neighborhood environments may play in developing social expectations and shaping behaviors.

Three Intertwined Definitions of Self-Regulation

Self-regulation refers to the development of children's ability to follow everyday customs and valued norms embraced and prescribed by their parents or caretakers and others. Self-regulation is a vital constituent of the *socialization* process. A broad construct, self-regulation encompasses a diverse set of behaviors such as compliance, the ability to delay actions when appropriate, and modulation of emotions, motor, and vocal activities as suitable to norm-based contexts. The *self* in self-regulation is an essential feature, and involves a sentient self – one that recognizes and understands the reasons for standards and evaluates one's own actions in relation to others' feelings and needs. Thus the hallmark of self-regulation is the ability to act in accordance with various family and social values in the absence of external monitors, across a variety of situations, but neither slavishly nor mindlessly.

A second meaning of self-regulation refers to various *physiological or psychobiological processes* that function adaptively to situational demands, and often do not involve normative standards. Examples include the regulation of intensity of arousal subsequent to emotion-producing events, or the control of centrally regulated physiological and perceptual systems to novel events. Centrally regulated systems include electrodermal responses, vagal tone and heart rate, and attention control. Variation in these responses is often studied for links to temperament styles, control of arousal states, and emotion control and coping (e.g., Ochsner and Gross, 2005; Kashdan et al., 2006; Goldin et al., 2008).

A third view of self-regulation comes from recent perspectives in cognitive science, which posits that motivation and

executive functions share roles in the *cognitive processes* underlying self-regulation. Here, with an emphasis on an individual's goals and the processes that shape the person's actions, a major role is given to the self's role and to evaluation of gains and losses. Autonomy, control, self-integrity, and efficacy are essential in order for the individual to be effective in the pursuit of desired goals. Within the motivational framework, substantial attention is directed to understanding how adults facilitate or inhibit the child's autonomy.

Socialization

Despite changing emphases in socialization, three principles remain a constant; these have implications for the development of self-regulation. First, most sociocultural groups expect primary authority figures, such as parents and other family members, to begin the active process of socialization. These individuals actively expose older infants and toddlers to family norms and practices. Later, these socializing agents will be joined by others who typically include teachers, peers, friends, and neighbors. New socializing agents may reinforce previous norms, expand the interpretation of norms, or introduce new ones. Children are expected to adapt their behavior accordingly.

Second, caretakers tend to be mindful – perhaps implicitly – of a child's developmental capabilities, the family's functional needs, and sociocultural standards when they teach norms. Protection of the child from harm seems to be the most salient *initial* child-rearing value. Then the content of caretakers' socialization efforts progresses to other family concerns, and from there to the broader context of neighborhood, community, and societal norms. Across sociocultural groups, there are assumptions that toddlers and preschoolers will learn a few specific family and neighborhood norms, whereas school-aged children will adopt family and cultural customs and moral standards, formal laws, and economic values. Adolescents are expected to prepare themselves for social, emotional, and economic independence using as infrastructure the norms of the family and culture.

The third principle is that socialization and self-regulation are adaptive, bidirectional processes. Children are not passive recipients in the socialization process. With the growth of their own cognitive skills and recognition of their own self needs, children show an increasing desire to have a say in defining the everyday customs that they encounter, and the ways customs are followed. Thus each succeeding generation in modern sociocultural groups modifies the content or enactment of customs and norms in some way. An implication for children is that effective self-regulation represents thoughtful, rather than indiscriminate, adherence to family practices and social norms.

Early experiences with caretakers is not the only social factor that influences self-regulation. Cultural scripts and social expectations can also contribute to self-regulation. Parental cautions about normative standards extend beyond the immediate family to peers, neighbors, and teachers, and focus on conventions and moral values, among other topics. Teachers, neighbors, and peers also play large roles in shaping behaviors during early childhood. In many cultures, e.g., Cameroonian Nso, child-rearing is shared between many women in a village.

Physiological and Psychobiological Processes

In addition to social learning, emotion regulation also relies on physiological resources, such as oxygen, and be influenced by physiological changes, such as fluctuations in hormones and heart rate. Negative emotions appear to require more resources than positive emotions according to many current studies. For example, regulation of negative emotions increases the need for increased oxygen consumption and ventilation, as well as causing elevated heart rate (Muraven and Baumeister, 2000; Gailliot and Baumeister, 2007; Lane et al., 2011). Although regulation of positive emotions use these resources too, they do not appear to be as physiologically taxing overall. Similarly, neurobiological studies demonstrate different brain activity in children when regulating negative emotions (Lewis et al., 2006). In particular, negative emotion regulation appears to consistently affect brain areas and processes associated with response inhibition. These brain processes appear to strengthen after early childhood, when more brain regions – such as the ventral prefrontal cortex associated with self control – become involved (Lewis et al., 2006).

Cognitive Processes of Motivation and Executive Function

In recent years, studies increasingly examine executive function and conscious control over one's own thoughts and behaviors. These are not single processes but rather composites of multiple processes, including working memory, inhibition, planning, and error correction. These processes are generally associated with the problem solving necessary for pursuits of goal-oriented behaviors (Carlson and Wang, 2007). The ability to flexibly self-regulate in order to pursue goals has been observed in young children and is considered necessary for successes later in life (e.g., Carlson, 2005; Meltzoff, 2007).

The Interrelationship between Social, Physiological, and Cognitive Processes

Successful self-regulating employs a combination of adequate social, physiological, psychobiological, and cognitive processes to interact appropriately with the surrounding sociocultural environment. For example, the adaptation of social and cultural elements may not be possible without enough physiological and psychobiological resources or the proper cognitive abilities to execute the task (Blair and Diamond, 2008). Such deficits may result in poor self-regulation exhibited through behavioral problems. Despite these underlying and converging factors, self-regulation is ultimately measured by behavioral output. Whether a child is able to control his or her behaviors and comply with the pressures and demands of peers, family, and life.

Many countries employ early intervention therapies and educational programs designed to address emerging problems in young children and to teach children compensatory skills for managing impulses toward dysregulation that may be caused by any number of underlying factors (Graziano et al., 2007). These programs have led to increased academic or professional success for many children. However, these programs also have normalizing effects that are not ubiquitously valued cross-culturally and potentially lead to better outcomes for certain learning styles.

Self-Regulation: The Early Years

The construct of self-regulation has heightened awareness of dysregulation and its long-term implications. Findings from related research point to long-standing problems when young children have difficulty with compliance, delay, and impulse control. To date, however, the developmental antecedents of these problems appear to be complex and context-dependent. However, two important developments occur in the second and third years that are key for the growth of self-regulation. These are emergent selfhood and the control of attention and consciousness.

It is well known that effective norm-based behaviors require reconciliation of conflicts between self-goals and social norm demands. Among mature individuals, these conflicts are often met with reflection about courses of action, informal appraisals of costs and benefits, and plans for making reparations should they be necessary. This complex cognitive strategy is not available to young children. Understanding how very young children begin to sort through competing self and social goals may provide insights into effective paths to self-regulation.

With respect to conscious learning about social norms, this almost certainly occurs, but when and how are not well understood. However, consciousness demands psychic energy, so it is in children's best interests to sort out those family and social norms that require relatively habitual responses from those that demand additional attention or memory efforts from themselves. How children learn to differentiate and classify standards may yield understanding about strategies useful for modulating behaviors in novel norm-based contexts, and why some children falter in these situations.

Concomitant Developmental Factors

The construct of self-regulation has heightened awareness of dysregulation and its long-term implications. Findings from related research point to long-standing problems when young children have difficulty with compliance, delay, and impulse control. To date, however, the developmental antecedents of these problems appear to be complex and context-dependent. However, two important developments occur in the second and third years that are key for the growth of self-regulation. These are emergent selfhood and the control of attention and consciousness.

With respect to conscious learning about social norms, this almost certainly occurs, but when and how are not well understood. However, consciousness demands psychic energy, so it is in children's best interests to sort out those family and social norms that require relatively habitual responses from those that demand additional attention or memory efforts from themselves. How children learn to differentiate and classify standards may yield understanding about strategies useful for modulating behaviors in novel norm-based contexts, and why some children falter in these situations.

A Self-Regulation Developmental Trajectory

Learning to deal with the norm-related requests of elders is a challenge, especially for young children who still have many cognitive and language limitations. It is not surprising that self-regulation takes years to mature into an effective process. An extensive database on topics related to self-regulation in the preschool years suggests that many additional factors contribute to self-regulation – from correlates including gender (many girls learn behavioral controls sooner than boys), temperament characteristics such as controlled attention and inhibition of motor acts, verbal skills, effective self-distraction, and competent use of strategies (Eisenberg and Fabes, 1992; Metcalfe and Mischel, 1999). The biosocial complexity of self-regulation has much room for error and compensation.

Active efforts by adults to socialize children gradually dovetail with children's growth of their own behavioral repertoire. Self-regulation gradually emerges when children understand the reasons for values and standards, possess a cognizant self, are able to suppress an immediate goal that runs counter to family norms, and voluntarily assume responsibility for their own actions across a variety of situations. This autonomous, sometimes conscious, effort to frame activities with normative values stands in contrast to early forms of compliance that do not rely on knowledge or self-awareness.

Processes underlying self-regulation require some ability to adapt to new or spontaneous social contexts, expectations, and demands. Effective self-regulation is by definition an adaptive, developmental process in that children have to discover how to meet their own self needs while in general following societal standards across many settings. The task is a changing one because each age period is associated with new socialization demands imposed by family, neighbors, teachers, other individuals, and the larger social context.

Abstract

Self-regulation refers to the extent to which people influence, modify, or control their own behavior (including thoughts and feelings) according to goals or standards. Goals are a key concept in models of self-regulation as they direct and guide cognition and behavior over time and across situations and thereby help to organize and structure perception, thought, and behavior into meaningful action units. However, the setting and pursuit of goals also requires self-regulation. Although the self-regulatory function of goals does not seem to change with age, the way goals are set and pursued does. The current article elaborates these processes in the framework of the model of selection, optimization, and compensation. Adapting to life-span changes in the availability of resources that are necessary for goal achievement, adults shift their primary goal orientation from the attainment of gains to the maintenance of functioning and the avoidance of losses. Moreover, goal focus appears to shift from a stronger focus on the outcomes of goal attainment to a stronger focus on the process of goal pursuit. These shifts in goal orientation and goal focus help self-regulation when faced with developmental goals and contexts requiring the optimization of functioning and performance in young adulthood, and the compensation of impending or actual decline and losses in later phases of adulthood.

Introduction

Self-regulation is a popular concept with more than 850 000 hits on Google Scholar (06/2013). The term refers to a variety of different processes located within the individual such as goal setting, planning, goal pursuit, progress monitoring, action control, delay of gratification, emotion control, or the resolution of goal conflict. Despite the heterogeneity of these processes that are subsumed under the term self-regulation, they have one function in common: They are all concerned with internal processes regulating thoughts, feelings, and actions. Very broadly, self-regulation can be defined as the extent to which people influence, modify, or control their own behavior (including thoughts and feelings) according to goals or standards (Baumeister and Heatherton, 1996). Although large parts of the current literature use the terms self-regulation interchangeably with self-control, some authors distinguish between these concepts. For instance, in Kuhl's conceptualization, self-control refers to processes that support the maintenance of an active goal, whereas self-regulation refers to "maintaining one's actions in line with one's integrated self" (Kuhl and Fuhrmann, 1998: 15). Similarly, Inzlicht and Schmeichel (2012) define self-control as a person's willpower, i.e., their self-regulatory *capacity* or *resources*.

Most of the literature converges on a definition of self-regulation as the processes by which a person aligns his or her behavior, thoughts, and feelings with personal goals. The concept of goals is therefore crucial for understanding self-regulatory processes. Goals can be defined as cognitive representations of desired (or dreaded) outcomes that a person intends to attain (or avoid) through action. They serve as knowledge structures that entail information about desired outcome states and the means that are functional for attaining them (Kruglanski et al., 2002). Goals direct and guide cognition and behavior over time and across situations and thereby help to organize and structure perception, thought, and behavior into meaningful action units (Freund, 2007). In that sense, goals foster self-regulation. However, goals also require self-regulation at all phases of the motivational process:

1. *Goal setting* (i.e., committing to investing means into attaining a desired outcome) requires the deliberative act of mentally simulating the outcomes of alternative goals and comparing their desirability. Such mental simulations are effortful and require self-regulation in that it would be less effortful to just take the first goal that presents itself or give in to impulses that promise immediate rewards.
2. *Goal pursuit* (i.e., the actual implementation of means in order to achieve a certain outcome) and maintenance (i.e., persisting in goal pursuit over time) require the monitoring of goal progress in order to determine if the means are adequate or need to be corrected and the investment of resources such as time, energy, or money. The initiation and maintenance of goal pursuit requires self-regulation in that competing behavioral options (that are often more pleasant than the goal-relevant behavior) have to be warded off.
3. If a goal is not achieved, one needs to decide at some point in time whether to disengage from the goal or to continue trying. Thus, the process of *goal disengagement* necessitates the reassessment of the likelihood of achieving the selected goal and the desirability of the outcome vis-à-vis opportunity costs (i.e., which other goals cannot be pursued because resources are invested in the target goal). Self-regulation is needed in order to not just give up goal pursuit at the first signs of setbacks or stagnation but, at the same time, to let go of a goal that has a very small likelihood of success or requires more resources than justified by the value of the outcome. Moreover, goal disengagement likely also requires emotion regulation (i.e., downregulating the emotional importance of the target goal).
4. Disengagement from a goal is often accompanied by goal *reengagement*. This can be either a new goal or a previously abandoned goal. To take up a previously abandoned goal might require even higher self-regulation than selecting

a goal for the first time because one has to overcome the obstacles or reasons that led to abandoning the goal in the first place.

We will later describe some of the intriguing findings that speak to the effectiveness of self-regulation. Before doing so, we want to emphasize the significance of self-regulatory processes from a developmental perspective.

Historical Overview: Emergence of the Recognition of the Active Role of the Individual in Shaping One's Life

The term self-regulation implies that people actively contribute to their developmental pathways and are not entirely under the control of external stimuli or biological processes. Although hardly controversial nowadays, it took a revolution – the 'cognitive revolution' – to introduce this notion into psychology in the 1960s when the field was dominated by behaviorism of the Watsonian or Skinnerian type. The importance of self-regulation for describing and predicting human behavior was stimulated by research by Mischel (1968) and Bandura (1969). Their research has convincingly shown that situational, external stimuli are but one factor influencing behavior and that, when attempting to understand human behavior, it is necessary to take sources of behavior regulation into account that lie within the individual (i.e., self-regulatory processes).

Developmental psychology was dominated by the view that development is best described either in terms of biologically determined maturation (i.e., unfolding of a biological program or blueprint) or as the result of a specific learning history in the sense of classic and operant conditioning. The latter view is exemplified in Watson's famous statement that if one were to give him a dozen babies he could – by arranging the environmental conditions – produce whatever adults one would wish to see (Watson, 1925). Watson also noted that he was overstating the role of the environment but he wanted to juxtapose the introspective approach to psychology focusing on inner states such as feelings and thinking with the behaviorist position. Although the interaction of biological and environmental factors for development was also stressed early on, for instance, by Piaget, the *proactive* role of the individual in creating his or her development has become more recognized since the 1980s (e.g., Brandtstädter and Lerner, 1999; Lerner and Busch-Rossnagel, 1981). In this perspective, development is viewed as the coconstructive interplay of biology, culture/society, and the individual (Baltes, 1997). On the one hand, individuals proactively shape their environment and place themselves into certain contexts. On the other hand, individuals react to their environment by continuously adapting and reacting to their physical, cultural, and social environment.

One important way in which individuals play a proactive role in their development is by choosing, committing to, and pursuing a set of personal goals such as wanting to become a teacher or deciding to have a child. The kind of goals a person develops and commits to is embedded in sociocultural, biological, and phylogenetic factors (Freund, 2007). The less behavior is under control of these factors, the more degrees of freedom a person has to choose what personal goals he or she wants to pursue and how. In other words, the less societal or biological influences structure and determine which, when, and how to pursue goals, the more influential are self-regulatory processes (Freund et al., 2009). Although less relevant for self-regulation, it might take a lot of self-control (following Kuhl's definition) to comply with external demands and norms, particularly when the respective goals do not match personal goals, preferences, and values.

In the following, we describe how self-regulatory processes shape development and how they themselves develop across adulthood.

Self-regulation across Adulthood: Personal Goals as Building Blocks for Life Management throughout the Life Span and into Old Age

Action-theoretical approaches view goals as central building blocks of self-regulation because goals structure and direct attention, emotions, and behaviors. Similarly, a number of developmental models have stressed the importance of goal-related processes and self-regulation for development, particularly in adulthood (i.e., the model of selection, optimization, and compensation (SOC) by Baltes and Baltes, 1990; the model of optimization in primary and secondary control by Heckhausen et al., 2010; the model of assimilative and accommodative coping by Brandtstädter and Renner, 1990). As one example, we present below the model of SOC. The *SOC model* (e.g., Baltes and Baltes, 1990; Freund, 2008) posits that, throughout the life span, individuals adapt to and bring about internal and external changes over time through the processes of SOC.

The importance of *selection* of goals is based on the assumption that biological, social, and individual opportunities and constraints specify a range of alternative domains of functioning at any given age and across the life span. For instance, the likelihood of women to conceive a child peaks in early adulthood and sharply declines in the late 1930s and 1940s. Most women are aware of this biological window of opportunity to become pregnant and take it into account when thinking about the goal to have a child. Similarly, educational goals are closely related to the opportunities offered by societies to obtain schooling, secondary, and tertiary education at a given age. Finally, examples for individual opportunities and constraints for personal goals are personality traits such as extraversion (making it easier to pursue social goals) or motivational dispositions such as being highly power motivated (facilitating the pursuit of goals involving making decisions and leadership). Biological, social, and individual factors interact in outlining the range of potential goals. The number of potential goals usually exceeds the amount of internal and external resources available to an individual, necessitating a reduction of the range of goals by *selecting* a subset on which to focus one's resources. Selection refers to the development, elaboration, and commitment to a limited number of goals. This does not only allow focusing one's resources but also gives direction to development (specialization). Moreover, goals organize behavior into action sequences and reduce the complexity of a given situation as they guide attention and behavior.

According to the SOC model, by delineating the range of goals on which to focus one's resources, selection is the first important step for successfully managing one's life through self-regulation. By specifying desired outcomes, selection sets standards against which to compare one's actual state of functioning, and the discrepancy can serve as a guide for behavior initiation, maintenance, or change (Carver and Scheier, 1998). In other words, to actually achieve the selected goals, *optimization* needs to take place. Optimization denotes the process of acquiring, refining, coordinating, and applying the means or resources that are necessary to reach the goals envisioned. The importance of optimization is illustrated in the research on performance that generally shows that performance is, to a large degree, a function of the acquisition and investment of goal-relevant skills and resources. In particular, the research on expertise has demonstrated that high performance depends to a significant degree on the deliberate practice of skills, including the acquisition of new skills, their refinement, their integration, and automatization. Thus, optimization is related to higher levels of performance and functioning that, in turn, are related to the accumulation of resources. Regarding self-regulation, optimization can be regarded as the second key concept of self-regulation as it refers to the actual investment of means into the attainment of selected goals.

The third component of the SOC model is *compensation*. Similarly to optimization, compensation is aimed at meeting the goal standards set by the selected goals. However, unlike optimization, compensation aims at counteracting losses in previously available goal-relevant means. This involves the substitution of lost means by using previously unused means or by acquiring new means. The objective is to maintain functioning or minimize losses when faced with resource losses.

A second form of managing losses is to restructure one's goals by focusing resources on the most important goals, adapting goal standards, or substituting no longer achievable goals (*loss-based selection*). The SOC model posits that loss-based selection is an important process of self-regulation as it allows focusing (or redirecting) resources adaptively when other means for the maintenance of functioning (compensation) are not available or would be invested at the expense of more promising goals. Loss-based selection involves two steps: (1) disengagement from the goal that is affected by losses, and (2) reengagement into alternative goals. Research has shown that disengagement without reengagement is not particularly adaptive when confronted with losses or blocked goals (Wrosch et al., 2003). This result underscores the important role of goals for self-regulation. The processes of disengagement are not yet well understood. Central questions concern if and how people can deliberately downgrade the emotional value and importance of goals in order to be able to 'let them go' without feeling one has failed which might undermine self-efficacy and feelings of control that are needed for further goal pursuit. Another question concerned with loss-based selection is how people decide whether to persist in goal pursuit despite setbacks and losses (compensation) or to disengage from further goal pursuit (Brandstätter and Schüler, 2013). The main issue in this regard is whether this decision resembles the choice between alternative goals during goal setting or is psychologically different because of anticipated or encountered losses threatening the maintenance of goals. This question taps into the psychological asymmetry of wanting to achieve gains or trying to avoid losses (e.g., Freund and Ebner, 2005). We will address the changes of gains and losses across adulthood next.

The SOC model stresses the importance of goals and adaption to developmental ecologies for self-regulation across the life span. Age-related changes in gains and losses in resources necessitate the flexible use of goal-related strategies. During childhood and through early adulthood, the ratio of gains to losses is highly positive. Across adulthood, however, losses become more prevalent and outweigh gains in old age. Adapting to this change in the availability of resources, goals shift from a predominant orientation on gains in youth and early adulthood to an increasing importance of maintenance and the avoidance of losses in middle adulthood and old age. This age-related shift is related to subjective well-being. One explanation of the age-differential effects of goal orientation toward gains and losses is that, with increasing age, the maintenance of functioning and avoidance of losses takes on a more positive meaning. Taken together, these results concerning goal orientation underscore that it is not only important for self-regulation *that* people set and pursue goals, but *how* they represent their goals depending on the availability of resources (in this context, gain vs loss orientation).

Is the shift from a primary goal orientation toward gains to an increasing importance of maintenance and the avoidance of losses also reflected in age-related differences in goal pursuit in the service of achieving higher levels of functioning (optimization) or maintaining functioning in the face of loss or decline (compensation)? On the level of self-report, optimization and compensation decrease from middle adulthood to old age. This is probably due to the fact that both processes refer to the investment of goal-relevant means that decline with age. Importantly, however, optimization and compensation are both related to subjective indicators of successful self-regulation (e.g., subjective well-being, absence of loneliness, subjective health) across adulthood and even into very old age. However, speaking for age-differential investment of resources in optimization and compensation, behavioral studies show that older adults pursue goals more persistently when they have to compensate for a loss, whereas younger adults are more persistent when aiming at optimizing their performance. A summary of the empirical studies on SOC is provided by Freund (2008).

Goal Setting across Adulthood

Probably one of the most influential models of self-regulation is Carver and Scheier's (e.g., 1998) cybernetic feedback model. The model defines goal setting as the process that creates a negative discrepancy between the current and a desired future state, which the person strives to overcome by employing goal-relevant means. It furthermore assumes that feedback loops on different levels of the goal hierarchy inform us about how well we do in reducing the discrepancy between the current and the desired future state. According to this model, self-regulation is the process of striving for an equilibrium between an actual and a desired state. One of the features that make this model

very fruitful is that it elaborates general processes of self-regulation that are not content-specific and that can be applied equally well to goals of varying levels of abstractness and including short- and long-term goals. Basically, the model predicts that people regulate the effort they put into pursuing a goal based on goal progress. Progress is defined as the rate of discrepancy reduction between the actual state and the desired end-state. If the person proceeds to the end-state faster than desired, positive affect arises. If progress is below the desired rate, negative affect arises. The affect accompanying goal pursuit, then, serves to regulate the selection and investment of goal-relevant means (i.e., positive affect: continuing to invest the same means; negative affect: changing the intensity of means investment or switching to different means).

From a developmental perspective, however, one of the shortcomings of this model is that it cannot explain goal setting and change in goals over time. If equilibrium is the desired end-state, why would anyone set goals for themselves and strive for change? According to a life-span perspective, social age-related expectations provide a reference for the kinds of goals that should be pursued at a given point in life. In addition, social expectations reflect age-related opportunity structures that guide a person toward goals for which resources are available and that, therefore, have a higher likelihood of being achieved than nonnormative goals. In this sense, age-related expectations represent important external constraints and guide goal setting across the life span and, thereby, impact self-regulation (Freund, 2007).

The Impact of Time Perspective on Goals

Age itself is not a meaningful explanation for psychological change across the life span. However, aging has psychological implications such as the accumulation of experience, the loss of cognitive and physical resources, and the restriction of future time perspective. These changes impact motivation and self-regulation in predictable ways. Research in the realm of socioemotional selectivity theory (e.g., Carstensen et al., 1999) has focused on the impact of time perspective on motivation. As people get older, their future time perspective becomes more restricted. Carstensen and her colleagues have proposed that viewing one's future as limited also impacts the kind of goals a person wants to pursue. Accordingly, younger adults (or people with an extended future time perspective) tend to strive for what Carstensen has labeled 'expansive goals,' i.e., goals with benefits that extend into the far future, specifically acquiring knowledge and making novel experiences. In contrast, older adults (or other persons with a more limited future time perspective, e.g., terminally ill patients) tend to favor goals with more immediate benefits, specifically experiencing meaningful positive emotions in the 'here and now.' These motivational differences are important for goal setting and pursuit in the realm of social relations. Socioemotional selectivity theory suggests that older adults, due to their shorter future time perspective, select their social contacts to be emotionally rewarding and meaningful, resulting in a smaller social network with close relationships than that of younger adults, who, due to their longer future time perspective, are less selective and socialize with others for emotional as well as informational reasons.

Generalizing the preference of older adults for emotionally satisfying social relations to information processing in general, socioemotional selectivity theory postulates – and provides empirical evidence – that older adults show a bias in attention and memory for positive compared to negative stimuli (Reed and Carstensen, 2012). This seems to suggest that older adults might habitually select goals that are directed at positive outcomes as both attention and memory favor positive information. However, recent evidence points to the flexibility of the preferential processing of positive or negative information depending on the goal of information processing: When attempting to minimize risks or potential losses, older adults seem to prefer negative information more than younger adults do (Depping and Freund, 2013). Taken together, research on the positivity effect points to age-related changes in the regulatory function of positive and negative information. Moreover, it underscores the important self-regulatory function of goals not only for behavior but also for information processing.

Setting Multiple Goals across Adulthood

People tend not to pursue single goals but strive for multiple different goals at a time. However, the availability of resources such as time, energy, attention, money, or social support restricts the number of goals that individuals can attend to at any given time. In line with the SOC model, several studies support that as a reaction to age-related resource losses, older adults are more selective and therefore report less personal goals than younger adults (e.g., Riediger and Freund, 2006). Other studies, however, did not report the age-related reduction in the number or self-reported personal goals (e.g., Ogilvie et al., 2001). These diverging results might be due to methodological differences in the way people report their goals: For example, people can report goals on different levels of abstraction. Whereas one person might list the single goal of 'increasing my physical health,' another person might list several more subordinate goals that nevertheless could be subsumed under this single goal, e.g., 'eat more healthily,' 'sleep more,' 'exercise two times a week.' It might be the case that the specific instructions in these studies interact with the level of abstraction of younger and older adults' goals.

Selectivity is not only reflected in the number of goals a person pursues. Goals also differ with regard to how much they facilitate each other. For instance, the pursuit of the goal 'running a marathon' might also help to accomplish the goal of 'losing weight.' Goals are more likely to facilitate each other when means of goal pursuit are multifinal as expressed in the proverbial "killing two birds with one stone." In contrast, intergoal conflict occurs when the pursuit of one goal (e.g., running a marathon) impairs the accomplishment of another goal (e.g., being more productive at work in order to receive a promotion) because both goals necessitate different means that draw on the same resources (e.g., time). Again underscoring the importance of selection, people who focus their goals on central life-domains also report higher goal facilitation. This contributes to self-regulation as facilitation leads to

higher engagement in goal pursuit and goal achievement. In contrast, goal conflict is related to lower everyday and habitual emotional well-being (Riediger and Freund, 2006). Interestingly, older adults show more intergoal facilitation and less conflict than younger adults. This might help them to better use their (restricted) resources efficiently for the pursuit of multiple goals.

Another way to pursue multiple goals in the face of limited resources is derived from Carver and Scheier's cybernetic feedback model, namely balancing. Balancing is a strategy that describes how people invest into the pursuit of one goal until a subjectively sufficient degree of goal progress has been achieved, and then turn to another goal. Balancing occurs only if people focus on goal progress rather than goal commitment (Fishbach and Dhar, 2005). Goal-directed action fosters the subsequent allocation of resources to other goals only if it is subjectively interpreted as an indicator of progress. If, in contrast, goal-directed action is interpreted as an indicator of goal commitment, resources will be continually allocated to the goal at hand. A focus on commitment thereby promotes the persistent pursuit of one goal rather than the balancing of multiple goals. As of yet, there exist no studies on age-related changes in the tendency to interpret investment into goals as goal progress or commitment, and the associated tendencies to balance multiple goals or sequence them.

Goal Focus: The Path or the Goal

Recently, the concept of goal focus has received considerable attention. It refers to the way people think about their goals and the goal components they tend to focus on (Freund et al., 2012). Goals encompass the cognitive representations of desired outcome states and the means that are functional for attaining them (Kruglanski et al., 2002). The extent to which a person focuses on these outcome states or the means may differ at any given time. A process focus denotes the higher salience of the means of goal pursuit (i.e., the 'how' of goal pursuit), whereas an outcome focus refers to a higher salience of the desired outcomes of goal attainment (i.e., the 'why' of goal pursuit). According to Vallacher and Wegner's optimality hypothesis (e.g., Vallacher et al., 1989), people perform better if they represent difficult, complex, and unfamiliar tasks in a concrete, process-related way that breaks these tasks down into their single steps. In contrast, performance in simple and familiar tasks benefits if they are represented in an abstract, outcome-related way that focuses on their meaning and effects. Extending this research to goals that are not technically difficult but pose self-regulatory challenges, studies have shown that focusing on the means rather than the outcomes of goal pursuit increases the pursuit of difficult goals such as dieting, exercising, or learning for an exam (for an overview of this research see Freund et al., 2012).

How does goal focus change across adulthood? A number of theoretical arguments speak for a shift from outcome to process focus as people get older. First, the developmental tasks of younger adults have an inherent outcome-oriented aspect. Young adults are still in the process of 'becoming,' i.e., their success is often measured in terms of the outcomes they achieve and their age-related appropriateness. For example, young adults strive to receive a college degree, find a job, find a partner, build a home, and found a family. During middle and into old adulthood, goals shift from attaining new and better outcomes to maintaining one's health, cognitive and physical resources, and close social relationships, and avoid losses. This shift in goal orientation from achieving gains to maintenance of functioning or the avoidance of losses also fosters a shift from focusing on (new) outcomes to a stronger process focus.

Moreover, older adults' shorter future time perspective might foster the adoption of a process-focused mind-set. On the one hand, the means of goal pursuit tend to be more concrete and context-embedded than the desired outcomes. They have to be implemented 'now' whereas the outcomes of goal pursuit are by definition a consequence, sequentially later in time. As for most goals, except for those that are pursued for purely intrinsic reasons (because their pursuit is fun), desired outcomes are psychologically more distant – their attainment is a consequence of goal pursuit and happens later in time. As older adults have a more restricted future time perspective, the process of pursuing a goal in the now and here might be of higher importance and more salient to them than the promise of achieving desired outcomes in the future. Focusing on the present might also come with a stronger focus on the process and the attempt to make this process as pleasant as possible. Empirical results support the hypothesis of an increase in process focus across adulthood (see Freund et al., 2012).

Outlook

The concept of self-regulation lies at the heart of models of successful development across adulthood. These models stress the importance of the setting, pursuit, and maintenance of goals as well as the disengagement from unavailable goals. Whereas the self-regulatory function of goals and goal-related processes does not seem to change with age, the content, orientation, and focus of goals adapt to life-span changes in resources and contexts.

Although models of successful development have acknowledged that the contexts in which people live are of major importance for their development, the exact processes and mechanism of how individuals use self-regulation to deal with varying contextual factors, constraints, demands, and opportunities, in order to promote successful development, have not yet been addressed. During childhood, adolescence, and young adulthood, biological constraints and social expectations regarding the kinds of goals to be pursued are relatively strong. In late adulthood and old age, there are fewer normative age-related expectations. This relatively greater social freedom might strengthen the importance of self-regulation through self-set personal goals. Going back to the distinction between self-control and self-regulation put forth by Kuhl, self-control might be more important in young adulthood, when external demands are stronger, and self-regulation might become more important in old age, when external demands are weaker. At the same time, however, resources needed for shaping one's environment according to personal goals decline in old age. Although it has been shown that older adults are still successful in pursuing their goals (e.g., Hennecke and Freund,

2010), the vicissitudes of old and very old age probably set boundaries to the extent that individuals can self-regulate their development.

Semantic Differential

Andrea Ploder and Anja Eder, University of Graz, Graz, Austria

Abstract

After its introduction in the 1950s, the semantic differential (SD) received enormous attention among psychologists and other social and behavioral scientists. Especially during the 1960s, its methodological details and possible fields of application were broadly and critically discussed. In 1969, David R.J. Heise reports more than 1000 papers on SD – a huge amount given the publication rates of that time. A good deal of this attention might be due to its promise to 'repair' a vital defect of behaviorist thinking, its smart use of factor analysis (a fashionable method at that time), and its connectivity to prominent debates on meaning in linguistics and philosophy of language. Especially Charles E. Osgood's claim for a universal structure of meaning in the EPA (evaluation, potency, and activity) structure points to the heart of the debate on semantic relativism.

In the early 1970s, behaviorism lost its position as the leading paradigm of psychology whereas cognitivism gained increased attention. The interest in the SD decreased. Still, SD joined the group of standard scaling techniques during the 1980s and 1990s. Today, it is applied by many disciplines worldwide, such as psychology, sociology, linguistics, marketing research, etc.

History of the Semantic Differential

The semantic differential (SD) was introduced and mainly developed by the US psychologist Charles E. Osgood (1916–91). It is a type of semantic rating scale measuring the connotative meaning of concepts like terms, objects, events, activities, ideas, etc. It captures the affective and cognitive components of respondents' attributions to selected concepts on a multidimensional level. Different from other rating scales, the SD is universally applicable – it measures associations, motivations, emotions, attitudes, etc., for almost every concept.

The original SD questionnaires contained a list of seven-point scales (−3; 0; +3) between bipolar, contrasting adjectives (e.g., good–bad, light–dark, social–unsocial) and a neutral zero point. Merely the poles of SD scales are labeled and the scales' intervals are assumed to be of equal distance (Figure 1).

The major purpose of the SD is to understand the connotative meaning of concepts, by measuring the connotative similarities, and differences within and between respondents' ratings. Factor analysis is the central procedure to analyze the proximity and distance between SD ratings and to determine the different dimensions by which they are represented in semantic space (Figure 2). In polarity profiles, the distribution of response patterns, the hetero- and homogeneity of the respondents' evaluations, is illustrated graphically (see Figure 3) and provides the basis for further correlation-based analysis.

Today, the SD is a standard scaling technique in the social and behavioral sciences. It is most prominent in psychology, but also used in linguistics, sociology, marketing research, and other empirically oriented disciplines.

Methodological Predecessors within the Social Sciences: Other Types of Scaling

Rating scales came up during the 1920s and 1930s, a period of formative methodic and methodological inventions. Due to their broad applicability, scaling procedures were quickly adopted in a lot of disciplines within the social and behavioral sciences. The SD was not the first scaling procedure for the measurement of attitudes. Still prominent are the Thurstone scale (a 'method of equal appearing intervals'), the Likert scale (a 'method of summative ratings'), and the Guttman scale (a 'method of scale analysis' coming up in the 1950s) (Edwards and Kilpatrick, 1948).

A Thurstone scale consists of statements, which are judged along graduations, i.e., 'very agree' to 'very disagree.' The concept was introduced in 1928 by the US psychologist Louis L. Thurstone. Thurstone scales are also assumed to be equidistant, but they do not operate with bipolar adjectives. Thurstone also was one of the founders of multiple factor analysis, a central method for the analysis of SD scales (Thurstone, 1948). The US social psychologist Rensis Likert (1932) introduced a five-point rating scale. Like the SD, it contains a neutral midpoint. Though, Likert scales do not use adjective lists but phrase positive or negative statements which together make up for a set of items (a 'summated rating scale'). Today, the Likert scale is by far the most famous and widely used scaling procedure within the social and behavioral sciences. A Guttman scale is dichotomous, each item being responded with either 'yes' or 'no.' It was developed by the US-Israelian sociologist Louis Guttman in 1944 and contains a set of phrased items, arranged in a consecutive order. Whoever agrees to an item on a higher level needs to agree to all items on the levels below.

The idea to measure not only attitudes but *meaning* with scales was brought up by the neobehaviorists John A. Glaze (1928) and Clark L. Hull (1933), who were among the first to scale associations. In a late autobiographical communication to a colleague, Osgood stresses the enormous influence of Hulls work on his thinking: "I had the heady feeling that

Figure 2 Semantic space resulting from SD data on political judgments. Reproduced from Osgood, Ch. E., Suci, G., Tannenbaum, P., 1957. The Measurement of Meaning. University of Illinois Press, Urbana, p. 121.

Figure 3 J. Bortz/N. Döring (2006: 186): (a) polarity profiles of concepts ‘masculine’ and ‘feminine,’ according to Hofstätter, P., 1973. Einführung in die Sozialpsychologie. Alfred Kröner Verlag, Stuttgart, p. 259; (b) two-dimensional conceptual system.

Figure 4 Factor analysis. Extraction of three leading factors: Evaluation, Potency, and Activity (EPA). Reproduced from Osgood, Ch. E., Suci, G., Tannenbaum, P., 1957. The Measurement of Meaning. University of Illinois Press, Urbana, p. 73.

here – with appropriate elaborations designed to bring *meaning* to the force – lay the key to even the most complex human behaviors, including language and social behavior generally" (quoted from Osgood/Tzeng, 1990: xi). Osgood's neobehaviorism can be read as an extension of Hull's approach to psychology. The psychologist Charles I. Mosier (1941) started to use bipolar adjectives in 11-point scales, covering an evaluative dimension (Osgood et al., 1957: 17) (see Chapter 3, Figure 4).

The development of scaling techniques between the 1920s and 1950s was accompanied by considerable efforts in statistical procedures, i.e., the introduction of correlation coefficients (Spearman, Tau, Pearson), factor analysis (Spearman; Thurstone), latent structure analysis, Cronbach's alpha, etc.

Theoretical and Institutional Context

The SD came up during a time of theoretical and methodological struggle within US-American psychology. When Osgood wrote his initial paper on the topic, the leading approaches in US psychology were learning theory and behavior therapy, both in the tradition of behaviorism. In line with its major theoretical conviction that human behavior can be exhaustively studied and explained with reference to its outside manifestations, behaviorist research was focused on observation and the measurement of physical reactions. Starting in the early 1950s, it got increasingly criticized – from neobehaviorists as well as representatives of *Gestalt psychology*, from linguists and philosophers of language. Being himself a neobehaviorist, Osgood was convinced of the general merits of behaviorism but saw at least one major problem: its inability to study mental events, which do not result in clearly observable patterns of behavior. The SD can be read as a methodological attempt to solve this problem.

When Osgood first started to work with the SD, semantics (i.e., the study of meaning in linguistic expressions) was a widespread topic in many areas of scientific engagement. What has later been referred to as the 'linguistic turn' concerned not only linguistics and philosophy of language, but also many other disciplines. From the late-1940s onwards, also psychology developed a strong interest in language (e.g., Skinner, 1957; Thurstone, 1948) in which Osgood was engaged from the very beginning. In 1952, the US Social Science Research Council (SSRC) established a Committee on Linguistics and Psychology (CLP) chaired by John B. Carroll and Osgood until its dissolution in 1961 (see Murray, 1998: 22f.). The committee was part of a program to support behaviorist social science within the SSRC.

At the University of Illinois in Urbana, Osgood was able to work with a research group focused exclusively on his project – the development of a theory and method for the measurement of meaning. He had the opportunity to do calculations with the ILLIAC 1, one of the very first electronic digital computers for nonmilitary use in the United States (see Osgood et al., 1957: i).

Osgood's most important reference point outside of psychology was psycholinguistics, a subfield of linguistics coming up in the late 1930s. With his work in the CLP, he was at the forefront of this discipline, focused on the psychological background of the acquisition and use of language capacities. In the early years of psycholinguistics, its general approach was behaviorist learning theory. From the early 1950s onwards, this focus changed. In 1959, the linguist and philosopher Noam Chomsky published a review of Burrhus F. Skinners' (1957) book on *Verbal Behavior*, where he convincingly showed that the acquisition and use of language cannot be studied from a merely behaviorist perspective. This finding considerably weakened behaviorism and was an important step toward the so-called 'cognitive turn' in psychology. Osgood, however, tried to establish a theoretical and methodological connection between behaviorist psychology and the psycholinguistic discussion of language and meaning. In 1966, when the attack against behaviorist psycholinguistics reached its provisional climax, he remained on the (neo)behaviorist side (Osgood and Tzeng, 1990: 18).

One of Osgood's central arguments is that structures of meaning are culturally universal. When he started to develop the SD, this idea was common sense among many scholars in different disciplines. A lot of psychologists searched for cross-cultural patterns during that time (e.g., Ekman and Friesen, 1971). In the late-1950s, the universality thesis got increasingly contested in linguistics and philosophy of language. Especially the writings of Edward Sapir and Benjamin Lee Whorf supported some kind of linguistic relativism. Their basic argument was that language affects thought and not the other way round. This implies that language cannot be the result of a universal structure of the human mind. It must be the result of contingent natural and social circumstances under which a language develops. The debate on linguistic universalism and relativism was a central issue in linguistics and philosophy of language at that time, a number of prominent scholars being involved. As we will see, Osgood never believed in the relativity thesis and hardly ever considered any arguments in its support. Instead, he dedicated most of his attention during the 1960s and 1970s to an empirical proof for a specific universal structure of affective meaning – the EPA (evaluation, potency, and activity) structure.

Despite of many possible connections, Osgood was not strongly engaged in contemporary philosophical debates on

meaning. In his 1952 and 1957 writings, he discusses several concepts but fairly ignores every approach that does not refer to behavior. His major point of reference is the behaviorist interpretation of Charles S. Peirce's pragmatist semiotics by Charles W. Morris.

Development and Early Career (1940s and 1950s)

The origins of the SD trace back to research on synesthesia – a neural linkage of two or more sensory or cognitive pathways. This linkage can result in the perceptive entanglement of very different entities – such as 'the number two,' 'green,' and 'warm.' With help of a primitive SD (two poles without scale), Theodore F. Karwoski (an early teacher and intellectual guide of Osgood, Osgood/Tzeng, 1990: 3), Henry S. Odbert, and others found out that some 'quasisynesthetic' phenomena are very widely spread. Their findings indicate that many semantic relations are shared by a very high percentage of people, independent from their cultural background (e.g., large–loud, near–fast, bright–happy, bad–dark, etc.). In the early 1940s, Osgood worked on synesthetic thinking together with Karwoski (Karwoski et al., 1942) and started to develop a scaling technique together with his friend and colleague Ross Stagner (Osgood and Stagner, 1941; Stagner and Osgood, 1941). In 1946, Stagner and Osgood used this technique for a study on social stereotypes. Previous studies had suggested a continuum between the poles, so they introduced a seven-step scale with a neutral zero point. In order to find out more about the forces behind the association game, they conducted a large test with 100 college students and 1000 items. They applied factor analysis and found three central factors with maximal differentiating power: evaluation, strength (later: potency), and activity (**Figure 4**). In the dimension of evaluation, adjective pairs like 'good–bad' and 'beautiful–ugly' showed high factor loadings. Pairs like 'large–small' and 'strong–weak' clustered in a separate dimension, which Stagner and Osgood called strength. Pairs like 'fast–slow' and 'active–passive' were assigned to the factor of activity. Together, the three factors made up the so-called EPA structure. In the following years, Osgood and his colleagues found many similar factor structures in other projects and started to assume that EPA represents the 'general dimensions of meaning.'

In 1952, Osgood introduced the SD as a tool for objective measurement of meaning. He was convinced that meaning is an important issue for behaviorist psychology but could not be captured with the methodological tools of the time. He discussed several theories of meaning and ended up with the following definition: "Words represent things because they produce some replica of the actual behavior toward these things, as a mediation process. This is the crucial identification, the mechanism that ties particular signs to particular stimulus-objects and not to others" (204). This conception is clearly neobehaviorist. It admits that cognitive processes affect human behavior but – apart from that – stays within the framework of behaviorist thinking. According to this definition, the central semantic relation ties a sign to an object – and the object stimulates a certain behavior. If the object is not at hand, the sign produces a cognitive replication – not of the object, but of the behavior toward the object – which we call meaning. In other words, the meaning of a sign is a *mediator* between the sign and a particular stimulus–response. For Osgood's purpose, it is crucial that the cognitive replication of a sign does not exhaust in its denotative meaning but always carries additional associations – its *connotative meaning*. In his widely received textbook on *Methods and Theory in Experimental Psychology* (1953), he explained why this kind of cognitive response is most likely to be the carrier of meaning: it is easy to perform, requires little energy, and therefore needs only little reinforcement to be learned. In the SD, Osgood exploited this idea methodologically, assuming that every mediational meaning response operates within a universal semantic space, which his scales claim to represent.

After a discussion of several methodological possibilities for the measurement of meaning, Osgood advocated a scaling approach. Scaling, he argued, provides for "controlled association in which the nature of the association is specified by definition of the scales (…) but the direction and intensity of association is unspecified" (222). Finally, he discussed the origins, logic, and merits of the SD and called for further research on its objectivity, reliability, validity, sensitivity, comparability, and utility (230 ff.). As will be shown, a lot of papers answered to that call. Especially between 1964 and 1974, the number of publications on the merits and limits of the SD were enormously high (see **Figure 5**).

In a 1954 case report for the *Journal of Abnormal and Social Psychology* (*A Blind Analysis of a Case of Multiple Personality Using the Semantic Differential*), Osgood and Zella Luria applied the SD to data of a multiple personality case. The material they worked with was data on patients with multiple personalities. The case of 'Eve' was very prominent in 1950s psychology (several teams of researchers worked on the case and in 1957, the story of 'Eve' is even be made into a film), and also this paper received wide attention. Osgood and Luria compared the semantic structure of Eves' three personalities, based on six SD testings with 15 concepts and 10 scales. The research design was very experimental and established a new area of application for the SD: clinical personality and psychotherapy research. Osgood did not systematically follow this line of research, but he used the data and his major findings in his 1957 book and came back to the case in the 1970s (see Osgood et al., 1976).

Until today, the most important work of reference for the SD is *The Measurement of Meaning* – a book published in 1957 by Osgood, George J. Suci, and Percy H. Tannenbaum. The volume summed up the central insights from the first years of research on the SD and can be read as a systematic introduction to its theory, methodology, application, and evaluation. Towards the end, the authors addressed some of the most prominent points of criticism and gave an outlook to important tasks for future SD research. The book received good reviews and reached the status of an academic bestseller.

Prominent Variations of the SD in the German-Speaking Countries

Although Osgood counts as the founding father and uncontested expert on the SD, other scholars developed prominent variations. Especially in the German-speaking countries, two other concepts received a lot of attention: The

Figure 5 Number of SSCI articles on the SD, 1950–2013. Data source: Social Science Citation Index ('Semantic Differential' in title (black); 'Semantic Differential' as a topic (gray).

Polaritätenprofil (or 'polarity profile') (Hofstätter, 1955/56) and the Eindrucksdifferenzial (Ertel, 1965).

The polarity profile was developed by the Austrian Social Psychologist Peter Robert Hofstätter in the course of the late-1950s. During his stay at the *Massachusetts Institute of Technology* and *The Catholic University of America*, Hofstätter got in touch with Osgood's writings and started to set up new bipolar adjective lists. Himself a researcher of groups, roles, and stereotypes, Hofstätter focused on group-specific differences toward meaning. The most famous example of a polarity profile, according to Hofstätter, included 25 contrasting adjective pairs measuring attributions to males and females (see **Figure 3**). It rated men's and women's qualities from 'soft' to 'tough' or 'submissive' to 'authoritative,' each on a seven-point scale. With this polarity profile, Hofstätter contributed to the research on prejudice and stereotypes as well as the sense of self and awareness of others (1973: 366). Analytically, Hofstätter started with a correlation of respondents' answers within and between polarity profiles. This correlation suggested a dimensionality, which he proved with help of factor analysis in a second step. Hofstätter's analysis resulted in two to three dominant factors as well, but he assessed the maximum four-dimensional system of connotative meanings according to Osgood as being 'primitive' (1973: 264). Hofstätter developed a three-dimensional model of personality including several factors beyond the EPA structure. According to him, at least 10–15 factors would be needed to capture the individual dimensionality of personality (Hofstätter, 1973). Furthermore, he assumed the semantic space to be historically and culturally grown (1963), not universal to all human beings, as Osgood had concluded.

A second influential variation of the SD is the *Eindrucks differential* (ED), developed by the psychologist S. Ertel in 1964/65. It contains 18 bipolar adjective couples and, in accordance with Osgood's EPA structure, assigns six adjective pairs to each dimension of the semantic space. In contrast to Osgood and Hofstätter, Ertel emphasized the *emotional* component of meaning. While Osgood had reduced affective meaning to the dimension of Evaluation, Ertel assumed emotionality to be central for the whole of the semantic space – including the dimension of potency and activity. Ertel agreed with the EPA structure of the semantic space, however develops an alternative interpretation.

One of the major differences between the US-American and European scientific communities of this time can thus be framed as a matter of style with significant methodological consequences. Most US scholars relied on Osgood's tested SD scales, whereas European scholars selected feature lists far more intuitively, in the manner of Hofstätter and Ertel (Schäfer and Fuchs, 1975: 119). In the European applications and validations of the SD technique, one can find references to Osgood, Hofstätter, and Ertel and, beyond, to national scholars who apply the SD in their 'own' cultural context.

Prosperity and Critique (1960s)

An SSCI count (Social Science Citation Index.) of articles concerned with the SD indicates an impressive prosperity during the 1960s and 1970s. **Figure 5** illustrates the results from a broad search on 'semantic differential' in all registered works of the index as well as a limited search in the contributions' titles, covering the time period from the 1954 to 2013. The vast majority of results are articles in journals, i.e., *The Journal of Psychology*, *Psychological Reports*, *Public Opinion Quaterly*, *Educational and Psycholgical Measurment;* occasional contributions were meeting abstracts, notes, and book reviews. Before the 1980s, almost all SD related articles addressed the SD in title, indicating a discussion of the technique as such. A close look into the papers shows that, most of them did not only apply the method but also dealt with its methodological background and/or question its empirical validation. In the 1990s, the number of articles dealing with SD tremendously increased, yet most of them merely applied the SD technique

rather than questioning its methodological implications. This increase is (in part) due to the growing number of countries and journals included in the Social Science Citation Index, in particular from the 1990s on.

Already at the beginning of the 1960s, the SD was widely recognized, in particular among US psychologists. Within this period, Osgood himself continued to verify and advance the technique as documented in his *Studies on the generality of affective meaning systems* (1962), *Comparative Study of Cultures* (1964), and the *Whys and Wherefores of E, P, and A* (1969). Therefore, the center of SD research remained at the University of Illinois, where Osgood, Tannenbaum, Suci, Luria, M.S. Miron, J. Lyle, and others further developed the theoretical and methodological framework of SD and practically applied it in their fields. Various articles on the SD were written at other US-American Universities, i.e., Washington, Michigan, Connecticut, Pennsylvania, Arizona, Berkeley, etc., covering different subfields of Psychology. In 1969, Osgood and Snider edited a sourcebook including nearly 1500 concepts for SD studies, which was also widely used.

The SD was discussed in various other fields during the 1960s, especially in education, marketing, communication, and theater studies. In Marketing Research, William A. Mindak was one of the first who dealt with *Fitting the Semantic Differential to the Marketing Problem* (1961). He used the SD to measure consumers' reactions to brands, products, companies, and their images. Robert F. Kelly and Ronald Stephenson (1967) in their approach focus on the analysis of consumers' decisions as support for retailers and consumer service institutions. In the field of theater studies, the major proponent of the SD technique was Raymond G. Smith who developed his own SD scales throughout the 1960s. Referring to Osgood's scales, he introduced 'speech correction concepts' (1962), tried to validate SD and tested its factorial structure in this specific field of research.

According to the SSCI, the most widely recognized contributions in the 1960s were Osgood's *Semantic Differential Technique in the Comparative-Study of Cultures* (1964) published in the American Anthropologist and David R.J. Heise's methodological discussion *Some Methodological Issues in Semantic Differential Research* (1969) published in the Psychological Bulletin.

Osgood (1964) is a central text for the proof of the universal (cross-cultural) validity of the EPA structure of affective meaning. By the end of the 1950s, Osgood claimed to have proven the generality of EPA for American English, but many critics doubted its transferability to other cultures and languages. In his 1964 paper, Osgood compared the United States with 16 other countries and language groups. From that time on, he established strong international networks, and the SD research teams around him became more and more international. The results of these studies show congruent results among the language groups in terms of the three dimensions – Evaluation, Potency, and Activity – which led Osgood to confirm his assumption of a generalized and universally valid EPA structure. In 1965, Osgood and the Japanese psychologist Yasumasa Tanaka compared three groups of people with different linguistic and cultural background who rated 24 *perceptual* signs by SD scales. Factor analysis brought about four different dimensions: dynamism, evaluation, warmth, and weight. This result was stable across all cultural groups and encouraged Osgood to engage in further EPA-related projects throughout the 1970s.

Critical methodological discussion and empirical testing of the SD in practical applications trace back to the 1950s and continued throughout the prosperous period. Still, they were particularly high during the 1960s. In his influential methodological discussion, David R.J. Heise (1969) referred to more than 1000 works on the SD, most of them dealing with methodological issues. Heise conceded that the SD is a useful standard method for social psychological research (1969: 421) but systematically highlighted the leading methodological questions and results of empirical tests carried out in the 1950s and 1960s: Among them, there were (1) the metric assumptions of SD scales (equal intervals between bipolar adjectives and the zero point), which Heise overall considered to be inadequate for some applications dependent on the concrete research work; (2) the different explanations for the sources of variance in ratings found by various scholars. In this context (a) bias errors due to scale-checking styles and social desirability were tested and (b) random errors were proven by means of reliability analyses, i.e., test–retest reliabilities. According to Daniel Kahneman – who wrote a dissertation on the SD in 1961 – variance is often partitioned as follows: "one-tenth due to subject-scale interaction, that is due to differences between subjects in the use of scales, one quarter due to bias and/or deviations of subjects' true scores from the population true scores, one quarter due to momentary deviations of subjects from their own true scores and two-fifths due to random error" (Kahneman quoted from Heise, 1969: 412); (3) Heise dealt with the structure of SD scales and stressed the empirically proven prominence of the three dimensions in semantic space: Evaluation, Potency, and Activity (EPA). Critique toward the EPA structure, in particular, included the number of factors and the number of concepts, which both, due to several empirical tests, were said to be underrated by Osgood. Some scholars found four or five factors, others discovered three subdimensions within Evaluation (functional, hedonic, and ethical value) (Heise, 1969: 413). Other scholars, in turn, found only two dimensions in their research. Moreover, it was individual differences, which in many cases counted for differences in the factorial results; a fact, which according to Heise deserved more attention. Heise concluded that Osgood's three dimensions were highly relevant, though further research would be needed to investigate the size and character of the semantic space; and (4) Heise referred to the assumption of concept–scale interactions, based on the different relevance of varying concepts or affected by the 'stimulus environment' (418) due to which he called for further validation.

Consolidation and Internationalization (Early 1970s)

Throughout the 1970s, psychology's leading paradigm gradually shifted from behaviorism to cognitivism. Although cognitive aspects had already been included in neobehavioral frameworks (i.e., in Edward C. Tolman's learning theory), it

took cognitivism many years to take over. As mentioned earlier, SD technique's methodological background is rooted in the neobehaviorist tradition: it includes behaviorist ideas but clearly refuses classical behaviorism. The SD survived the 'cognitive revolution' and became a standard technique of scaling. In the early 1970s, its prominence further increased, methodological discussion continued as well as concrete applications, reliability, and validity testing. Furthermore, it got increasing attention outside psychology and outside of the United States: The SSCI shows articles from Venezuela, Brazil, Italy, Spain, Germany, Russia, Japan, India, Czechoslovakia, etc., thus both, an internationalization and increasing differentiation in various fields of research took place.

One of the most recognized articles on the SD in the 1970s was published by Kalman J. Kaplan (1972) and dealt with the *Ambivalence-Indifference Problem in Attitude Theory and Measurement*. Kaplan modified the SD in order to draw a distinction between ambivalent and indifferent responses. While Osgood understood the midpoint of SD scales as being *neutral*, based on the assumption of reciprocal antagonist bipolarity, Kaplan raised the question of *ambivalent* responses. In his modification, he suggested to separate SD scales into a positive- and a negative component-scale. "Three independent measures are thus generated by this technique: first, the usual bipolar attitude (A), second, its positive or "liking" component (Ap), and third, its negative or "disliking" component (An)" (366). The different components thus could be correlated. Based on the component model, Kaplan furthermore developed a model, which allows to seperate the 'total effect,' 'ambivalence,' and 'polarization' of SD scales. Kaplan's considerations on scalings' midpoints finally turned out to be of great importance for scaling techniques in general.

Osgood himself had a clear focus during the 1970s: he wanted to proof the universality of the EPA structure. He continued and expanded his works on *Cross-Cultural Universals of Affective Meaning* (1975), published together with psycholinguists and his (former) research affiliates M.S. Miron and B. May. Their enthusiasm for cross-cultural comparisons can be understood from different perspectives: In the 1970s, worldwide networking in the field of research but also in politics and other social areas started anew. Many disciplines were interested in differences and similarities between cultures in order to help preventing further conflict. In this line, scholars were also fascinated by the cross-cultural similarity of human beings after World War II, as they provided a plausible justification of the 'new' egalitarian views. Last but not least, the framework requirements of technical progress and IT were a highly important prerequisite to manage the huge amounts of country comparative data in the 1970s.

In their 1975 book, Osgood, Miron, and May stressed the fact that "cross-national research, by its very nature, must be entangled in the cultural and political matrix of the world at the time" (7). Osgood, Miron, and May broadly discussed the conceptual and methodological limitations of their own cross-national research in the field of cross-linguistics. They reflected on the 'westernization' of research meaning – i.e., the application of Western concepts to the analysis of non-Western countries. To deal with this bias, they asked native speakers from each language/culture community to translate the scales, initiated deep-going pretesting procedures for each country, and made efforts in sampling technique and data collection to solve the problems of within-country representativeness and between-country comparability. More than 20 countries (e.g., Afghanistan, Belgium, Costa Rica, Delhi, Germany, Hungary, Italy, Iran, Japan, Malaysia, Mexico, Sweden, Turkey, the United States, etc. (1975: 194)) participated in this new study, Indo-European language groups being overrepresented. The superordinate goal of the project was to prove the cross-cultural validity of the EPA structure. Osgood, Miron, and May started with systematically controlled data from the English-speaking countries and included the non-English speaking countries in a second step. As their findings clearly supported the idea of a general EPA structure, they assumed that "the EPA-system found for English-speaking Americans is linguistically and culturally universal for the human species" (1975:112).

Apart from this, Osgood advanced another sideline of his early work: the application of the SD as a tool for clinical psychology and therapy of schizophrenia. In 1976, he published a 'continuation' of the blind analysis from 1954 together with Luria and S.W. Smith. On behalf of the therapist R.F. Jeans, a new case of multiple personality, 'Evelyn' was systematically compared with the 'three faces of Eve,' in order to improve the SD as a tool for clinical purposes. The 15 concepts used for the case of 'Eve' are added on by 10 further concepts, specific to the case of 'Evelyn' who, according to Jeans, inherited three personalities, 'Mary,' 'Gina,' and 'Evelyn.' Osgood, Luria, and Smith possessed basic information on the patient's family background and anamnesis. As Eve, Evelyn rated herself and her family members along Osgood's SD scales, with different answers for each personality within the three dimensions of the semantic space: evaluation, potency, and activity. Osgood, Luria, and Smith systematically analyzed the specific response patterns of each personality of 'Evelyn' and compared it to the case of 'Eve.' They discussed the results and interpretations of the blind analysis with the therapist Jeans, who agreed with their findings. He used them for his therapeutic work and even included them in one of his books on diagnosis and therapy of multiple personalities (1976: 274).

In 1975, the German sociopsychologist Reinhold Bergler published an anthology in which he, Brigitte Diehl, Albert Fuchs, Reinhard Oppermann, and Bernd Schäfer commented on the status quo of international research on the SD and discussed its methodological foundation and fields of practical applications. Bergler questioned the uncritical application, lack of validation, and theoretical deepening and demanded to make the method itself a central object of investigation (1975: 11ff.). This demand sums up the superior concern of the anthology. In particular, he called for systematic intra- and interindividual analysis as well as investigations considering a longitudinal perspective in order to capture group differences and meanings' changes over time (1975: 15). He stressed the

importance of individually selecting the investigated population and their specific associations, and consequently called for 'obligatory' pretesting methods (1975: 23). In this line, Bergler and his colleagues criticized the universal application of SD by both Osgood and Hofstätter. Among others, Bergler, Schäfer, and Fuchs, sharply questioned the reduction of the semantic space to three dimensions and stressed the existence of intercultural differences in language use. Given the demand to improve SD scaling, Schäfer and Fuchs, on the one hand, called for more extended testing of SD scales' selectivity, to introduce coefficients in order to prove intraconcept variability. On the other hand, they suggested tests for the selectivity of respondents' ratings (1975: 131ff.).

Differentiation and Pluralization of Applications (Late 1970s, 1980s and 1990s)

In the late-1970s, methodological interest in the SD decreased. It became part of the standard repertoire in a lot of disciplines, still predominantly in psychology, but did – as a method – not receive a lot of attention anymore. One reason might be that all relevant arguments had been made and there was nothing left to say. The concept proved to be useful for some research contexts, documented in a great variety of different applications of the SD, however inappropriate for others. Osgood's argument for the universality of the EPA structure did not convince his colleagues and therefore seemed to be forgotten soon. Scholars continued to apply the SD technique, independent from its methodological, historical, and theoretical background. Another reason might be the growing interest in cognitive psychology, which absorbed the attention of the community and outdated some general convictions of Osgood's work. Beyond, new scaling techniques (e.g., Rasch scales and Mokken scales) were established, which attracted various scholars and confronted them with new questions.

Summary and Today's Significance

After its introduction in the 1950s, the SD received enormous attention among psychologists and other social and behavioral scientists. Especially during the 1960s, its methodological details and possible fields of application were broadly and critically discussed. In 1969, Heise reported more than 1000 papers on SD – a huge amount given the publication rates of that time. A good deal of this attention might be due to its promise to 'repair' a vital defect of behaviorist thinking, its smart use of factor analysis (a fashionable method at that time), and its connectivity to prominent debates on meaning in linguistics and philosophy of language. Especially Osgood's claim for a universal structure of meaning in the EPA structure pointed to the heart of the debate on semantic relativism.

In the early 1970s, behaviorism lost its position as the leading paradigm of psychology whereas cognitivism gained increased attention, and the interest in the SD decreased. Still, SD joined the group of standard scaling techniques during the 1980s and 1990s. Today, it is applied by many disciplines worldwide, such as psychology, sociology, linguistics, marketing research, etc.

Semantic Memory

Julie S Snowden, Manchester Academic Health Sciences Centre, Institute of Brain, Behaviour and Mental Health, University of Manchester, UK; and Greater Manchester Neuroscience Centre, Salford Royal NHS Foundation Trust, Salford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Semantic memory refers to our conceptual knowledge of the world. Understanding of semantic memory has come from several sources: cognitive studies of healthy individuals, computational modeling, patients with disordered semantic memory due to brain disease, and brain imaging and stimulation. The converging evidence indicates that semantic memory involves distributed brain networks, which, at least in part, are linked to the sensory processes involved in perception, action, and language. Whether there is also representation in amodal format remains an area of contention. Knowledge of the world, beyond word and object meanings, is a challenge for future studies of semantic memory.

What is Semantic Memory?

Semantic memory represents a person's conceptual knowledge and understanding of the world. It includes knowledge of the meaning of words, objects, and other percepts experienced directly through the senses as well as the more abstract encyclopedia of facts that one acquires over a lifetime. Knowing that the word 'water' refers to a liquid that is equivalent to 'acqua' in Italian and 'agua' in Spanish is part of semantic memory. So too is knowing that water quenches the thirst, is used for making tea, is slippery when frozen, and can scald when boiled, and that it is possible to drown in water if you cannot swim. Semantic memory encompasses all that one knows. It is crucial in enabling a person to function and interact with the outside world.

Historical Background: Development of Knowledge about Semantic Memory

Semantic-Episodic Memory Distinction

The delineation of semantic memory as a distinct form of memory is credited principally to Endel Tulving who distinguished it from episodic memory (Tulving, 1972). Semantic memory was defined as information that is shared between people within a culture and not tied to a specific temporal or spatial context. By contrast, episodic memory was construed as memory for events defined in terms of time and place and unique to an individual person. Thus, knowing that London is the name of the city where the 2012 Olympic Games were held is part of semantic memory, whereas remembering a visit to London to attend an Olympic event constitutes episodic memory.

Early Language Models of Semantic Processing

Tulving originally construed semantic memory in terms of a mental thesaurus, and hence essentially dealing with linguistic concepts. The language-related focus reflected much of the early work on semantic memory, and indeed, 'semantics' remains a central issue in understanding language.

Hierarchical network model

The term 'semantic memory' had been used prior to 1972 by computer scientist Ross Quillian, who was attempting to program machines to understand language. A central question was how meaning is represented. In his hierarchical model (Collins and Quillian, 1969), concepts were represented as nodes in a network, each associated with a number of properties. In the case of the concepts canary, bird, and animal, for example, the subordinate level concept 'canary' is more closely linked to the superordinate concept 'bird' than the overarching superordinate 'animal.' The finding that it takes longer to verify the sentence 'A canary is an animal' than 'A canary is a bird' was taken as support for the hierarchical account. However, by analogy, the model ought also to predict that it would take longer to verify 'A dog is an animal' than 'A dog is a mammal.' Yet, this is not so. Moreover, the model does not explain why it is easier to verify prototypical examples of a category, such as 'A canary is a bird,' compared to atypical examples, such as 'A penguin is a bird.'

Spreading Activation Model

The 'spreading activation' theory of semantic processing represented a less rigidly structured revision of Quillian's network model. It incorporated the idea of semantic distance, highly related concepts being located closer together than unrelated concepts. The model also allowed different types of links, including class membership 'X is a Y,' attributes 'X has a Y' as well as negative information 'X is not,' 'X cannot Y.' The model proposed that when a concept is processed, activation spreads out along the paths of the network, the activation from the source node becoming progressively more attenuated with outward spread.

Feature Comparison Models

An alternative to the spreading activation model was the feature comparison model, of which major proponents were Smith et al. (1974). The model assumed that the meaning of a concept is determined by a set of defining and characteristic features, and that verification of a sentence such as 'A canary is a bird' involves comparing the features of 'canary' with those of 'bird.' The model correctly predicts that prototypical

examples of a category will be verified faster than atypical examples because of the greater overlap in features. A limitation is that the model does not readily account for differences between the sentences 'A canary is a bird' and 'A bird is a canary.'

These early models share the common principle that concepts contain component properties or features, a notion that underpins contemporary thinking about semantic memory.

Semantic Memory Is More than Words

Schemas and Scripts

In the 1970s, a number of scientists including Marvin Minsky, David Rumelhart, and Roger Schank argued that semantic memory must encompass more than simple word concepts and adopted approaches to comprehension that involved larger chunks of information, referred to as frames, schema, or scripts. Schank and Abelson (1977) proposed that people build up schema/scripts that represent commonly experienced activities and events. Thus, a schema for buying goods in a shop would incorporate the notion of exchanging goods for money. A schema for going to a restaurant would include the notion of choosing from the menu, ordering from a waiter, and so on. Schema varies according to culture. In some cultures, the purchase of goods would incorporate the notion of bartering, whereas in other cultures it would not. The notion of schema based on culturally relevant experience enables people to understand sentences and draw appropriate inferences when information is not explicitly stated. For example, the sentence 'John dropped into the Queen's Arms on his way from work' is likely to be interpreted by a British listener as meaning that John went to a pub called the Queen's Arms where he had a drink and then he went home afterward (not that he went to Buckingham Palace in London and fell into the arms of the Queen). Schema models of semantic memory have been explored through computer modeling. They continue to have relevance, discussed later.

When Semantic Memory Breaks Down

Semantic Dementia

Early studies of semantic memory came from the fields of computer science and experimental psychology, and human studies involved healthy volunteers. A crucial development came from an entirely different quarter. In 1975, Elizabeth Warrington, neuropsychologist working at the National Hospital, London, described a series of patients who had difficulty recognizing objects as the result of degenerative brain disease (Warrington, 1975). A distinction had long been drawn between two forms of disordered visual object recognition: apperceptive agnosia, characterized by a difficulty in integrating visual sensory information into a coherent percept, and associative agnosia, characterized by loss of understanding of percepts that are themselves normal. Warrington's patients showed the associative type. Warrington appreciated, however, that the patients' loss of understanding extended beyond object recognition; they also had difficulty understanding object names. That is, they could no longer remember the meaning of words and objects. Yet, those patients were not amnesic in the traditional sense. Warrington characterized the patients' disorder as a 'selective impairment of semantic memory.' Since then, the multimodal yet circumscribed nature of patients' disorder has been widely reported (e.g., Hodges and Patterson, 2007; Snowden et al., 1996). Snowden introduced the term 'semantic dementia' to capture the widespread nature of the semantic breakdown.

Impact of Semantic Loss

In semantic dementia, words are gradually lost from a person's vocabulary and the conceptual distinctions between related words are progressively eroded. People with semantic dementia make semantic errors in naming, such as 'dog' for lion and 'banana' for lemon, because they can no longer discriminate conceptually between a dog and a lion and between a banana and lemon. They show loss of understanding of words spoken by others and may ask what words mean (e.g., 'lion, what's lion?'). Communication becomes severely compromised.

People with semantic dementia may misuse objects because, although they perceive objects normally, they no longer understand what each item is for. They may be perplexed by environmental sounds (e.g., a clap of thunder). They may attempt to eat inedible objects because of inability to discriminate edible from inedible substances. They may ignore danger signals such as the smell of burning, the taste of stale food, and the rapid approach of a fast car because those signals carry no significance. The consequences underscore the fundamental practical role of semantic memory.

There are, nevertheless, areas of preservation. Despite failing to recognize goods in the supermarket, people with semantic dementia may remember the aisle and shelf from where they obtained goods on a prior supermarket visit. They may not recognize the face or name of their hairdresser, yet have no difficulty remembering the time of their appointment at the hairdresser's and how to get there. Such apparently surprising disparities reinforce Tulving's theoretical distinction between semantic (conceptual) and episodic (event) memory.

Breakdown in semantic memory is not restricted to semantic dementia. It may occur in association with a variety of brain disorders, including Alzheimer's disease, herpes simplex encephalitis, and temporal lobe epilepsy. However, semantic dementia provides the most striking and purest example of semantic breakdown, and therefore constitutes a natural model for understanding semantic memory. Much of what is currently known about semantic memory has come from patients with semantic memory disorders.

Technology Provides a Window on to the Neural Basis of Semantic Memory

In recent years, advances in brain imaging have provided a complementary source of information to patient data, opening up the possibility of exploring directly the anatomical basis of semantic memory. Converging evidence emphasizes the importance of the temporal lobes. Disordered semantic memory due to a variety of etiologies is associated with damage to the temporal lobes. Functional imaging studies, using positron emission tomography and functional magnetic

resonance imaging, show activation of temporal regions when healthy volunteers carry out semantic tasks, and transcranial magnetic stimulation of temporal regions disrupts the efficiency of semantic processing.

The precise regions within the temporal lobe that are most critical have been subject to debate. Some have argued for the importance of the anterior temporal lobes (Visser et al., 2009), not least because of the severe anterior temporal lobe atrophy associated with semantic dementia (Mummery et al., 2000). Others have implicated posterior temporal regions (Martin, 2007). The relative contribution of these brain regions is directly relevant to contemporary models of semantic memory, considered below. Of importance too is the question of the role of the two hemispheres (see Section Modalities of Knowledge) and of the brain regions outside the temporal lobe (see Section Categories of Knowledge).

Theoretical Questions That Have Informed Current Thinking about Semantic Memory

The following are some key neuropsychological questions that have shaped our current state of knowledge about the organization of semantic memory.

Is Superordinate Category Knowledge More Resistant to Disruption than Subordinate Knowledge?

An early question, directly pertinent to Quillian's hierarchically organized model of semantic memory, was whether superordinate category knowledge is more resistant to disruption from brain disease than lower order levels of knowledge, representing information about properties or attributes. It is certainly true that semantic dementia patients are able to classify words or pictures according to their broad class (e.g., animals versus objects; edible versus nonedible) better than they can categorize within a class (e.g., cats versus dogs; apples versus oranges). Nevertheless, it does not necessarily follow that breakdown of semantic memory follows a systematic path from most specific to most general. The strict hierarchical model would assume that access from a lower to higher level of the hierarchy requires traversing intervening levels. A robin should not be correctly classified as an animal if it cannot first be classified as a bird. Yet, patients with semantic disorder do indeed classify robins as animals, without knowing that they are birds. Moreover, they may recognize their own object without recognizing alternative versions of the same object, which would not be predicted if generic category knowledge were preserved.

An alternative argument, to account for the superior ability to classify across compared to within a class, is that if knowledge of some semantic features is lost then the remaining impoverished information will be better able to support broad (e.g., categorical) rather than fine-grained (i.e., exemplar) distinctions. This is particularly so because the features most likely to be retained are those that occur with greatest frequency, being shared by most members of the category (e.g., 'has legs' for animals), whereas those most likely to be lost are those least common and shared by fewest members of the category (e.g., 'has stripes'). Hence, impoverished feature knowledge may be sufficient to allow a tiger to be identified as an animal as opposed to a fruit but not to be distinguished from a dog. Such an account, which is in tune with current thinking, reflects a shift in emphasis away from organizational hierarchy per se toward the types of feature information required for specific semantic tasks.

Modalities of Knowledge: Can They Break Down Selectively?

Semantic dementia affects all sensory modalities. It impairs the ability to understand the meaning of words, faces, objects, tactile stimuli, nonverbal environmental sounds, tastes, and smells. An important question is the relationship between modalities. Does decline inevitably occur in parallel across modalities or can one modality be affected more than another? The question has commonly been framed in terms of whether there is a unitary or multiple semantic systems. However, there are more far-reaching implications. A unitary system assumes that concepts are represented in amodal form, divorced from modality of input. By contrast, a multiple-systems view proposes systems linked to a particular modality; for example, verbal semantics versus visual semantics.

This question posed by neuropsychologists parallels a central debate in the cognitive psychology literature of the 1970s and 1980s. Authors such as Fodor (1975) took the view that concepts are represented in the brain in a formal, amodal, and abstract manner, unrelated to the brain processing of sensory motor functions. The assumption was that modality-specific perceptual systems process information up to the level of structural description, which permits access to a unitary, amodal semantic system, where no trace of sensory motor mechanisms persist. By contrast, others such as Allport (1985) argued that concepts are represented in the brain in the same format in which they were constructed by the sensory motor system.

It is indisputable that people with semantic dementia may fail to recognize an object name (e.g., glove) while continuing to recognize a picture of a glove or the glove itself. One obvious interpretation is that this is evidence of modality-specific meaning systems in the brain (McCarthy and Warrington, 1988). Damage to an amodal semantic system would not predict such dissociated performance. An alternative explanation, however, is that the disparity is simply an artifact of task difficulty. There is a more direct mapping between surface form and meaning in the case of pictures and objects: they give direct clues to meaning, whereas words are arbitrary labels. Patient's degraded knowledge may be sufficient to support performance on the object but not the word recognition task. Less easy to dismiss as artifact are findings of dissociated knowledge of famous faces and names. Faces and names are equally arbitrary. Neither gives direct cues to identity. Moreover, superior performance has been demonstrated in both directions: better knowledge of names in some patients and faces in others. Furthermore, there is a systematic relationship with site of atrophy: poorer knowledge of names associated with greater left- than right-sided temporal lobe atrophy and poorer knowledge of faces with the converse. Such findings argue for the contribution of both hemispheres in semantic memory, and importantly, a differential role of the left and right hemispheres, with the left temporal lobe being more important for verbal and the right

for visual semantics (see Gainotti, 2012 for review of evidence). Proponents of an 'amodal semantics' view offer the counterargument that dissociations reflect impaired connectivity to modality-specific systems. Thus, left temporal lobe damage would have greater impact on connectivity with language systems located in the left hemisphere (Mion et al., 2010). The debate remains central to contemporary models of semantic memory representation.

Categories of Knowledge: Can They Break Down Selectively?

A crucial early observation was that some patients with disordered semantic memory had disproportionate impairment for certain categories of knowledge (e.g., knowledge about animals or fruits) with relative sparing of other categories (e.g., household utensils).

Early debate rested on whether such dissociations were genuine or artifacts of differences in frequency, familiarity, or typicality of the items for which knowledge was tested. It is now established that real dissociations do indeed occur, since they persist even when confounding factors are rigorously controlled. Moreover, dissociations are observed in both directions: superior knowledge of living things in some patients and nonliving thing in others, better abstract word knowledge in some and concrete word knowledge in others, better verb than noun knowledge in some and the reverse in others, and better number than word knowledge in some and the reverse in others. Crucially, category differences are mirrored by anatomical differences. Disproportionate disruption to knowledge about living things has been associated with damage to temporal lobes/ventral pathways and nonliving things to frontoparietal/dorsal pathways. Disproportionate noun impairment is linked to temporal and disproportionate verb impairment to frontal lobe dysfunction. Number knowledge depends crucially on the parietal lobes, which are spared in semantic dementia.

The interpretation of such dissociations in knowledge is nevertheless controversial. An influential view (the functional-sensory hypothesis proposed by Warrington and colleagues) was that category dissociations result from differences in the weightings of properties that define a concept and the sensory processing channels through which information was originally acquired (Warrington and Shallice, 1984). Household objects such as 'cup' and 'bowl,' it would be argued, are distinguished largely by their different functions, whereas fruits such as 'orange' and 'banana' are distinguished predominantly on the basis of sensory properties such as color, shape, texture, taste, and smell. A disruption to knowledge about sensory attributes would result in disproportionately severe impairment for animals compared to household objects, whereas disruption to knowledge about functional attributes would produce the reverse. The underlying assumption is that information is organized in the brain by property rather than category.

A contrasting account (the domain specificity hypothesis), advanced by Caramazza and Shelton (1998), argued that different categories of knowledge are supported by distinct neural networks, so they are regionally segregated in the brain. The finding in semantic dementia that number knowledge (including understanding of quantity and arithmetical skills) is remarkably preserved in comparison with knowledge of words would be a good example of apparent domain specificity. So too would the observed dissociation in some patients between understanding of nouns and verbs. More problematic for the domain specificity account is that, for the most part, category differences are relative. Patients with disordered semantic memory typically show partial information loss about concepts across multiple domains, a finding that would be predicted by the functional-sensory account because of its emphasis on relative weightings of attributes rather than category per se. Regardless of their relative merits, what is crucial is that both *functional-sensory* and *domain specificity* carry the notion of distributed representation of semantic memory across different brain regions, a notion that is supported by brain imaging and underpins current thinking about semantic memory.

Beyond the Functional-Sensory Distinction: Attribute Knowledge and Its Neural Basis

Warrington and colleagues recognized early on that the broad distinction between living and nonliving things was an oversimplification, and within the framework of the functional-sensory account a wide range of dissociations ought to be possible, reflecting relative degrees of disruption to particular sensory or nonsensory attributes. The conceptual distinction between a lemon and a lime, it would be argued, relies heavily on color, taste, and smell, but little on visual form, sound, or movement. By contrast, form, sound, and movement are relevant dimensions in the conceptual distinction between a dog and a cat. Some nonliving things, such as a cup and a jug, are manipulable, so afford specific motor actions with respect to them (e.g., grasping, pouring), whereas other nonliving things, such as a house, are nonmanipulable so are not conceptually associated with a motor action. The evidence indicates that patterns of breakdown and dissociations in performance in semantically disordered patients are indeed more subtle and diverse than the gross categorical distinctions or division between living/nonliving things would imply. Semantic dementia patients have, for example, been reported to show disproportionately impaired knowledge about color-related compared to form-related words, and about action words referring to face movements and speech acts than actions performed with hand and arm (Pulvermüller et al., 2010).

There is a wealth of functional neuroimaging data that complement the patient data (Martin, 2007; Martin and Chao, 2001; Thompson-Schill, 2003). The brain regions active during object identification have been found to depend upon the intrinsic properties of the object presented. Thus, animal naming has been found to activate occipital regions involved in visual processing in addition to temporal regions, whereas naming tools activate the left premotor area involved in object manipulation. Moreover, retrieval of knowledge about specific attributes of an object involves activation of the same brain regions (albeit with a slight anterior shift) as those involved in perceiving and using those objects. Thus, retrieving visual attribute knowledge (e.g., whether a camel has a hump) involves activation of visual association cortex, color knowledge retrieval activation of ventral temporal cortex involved in color processing, retrieval of size

information activation of parietal regions involved in spatial processing. Pulvermüller et al. (2010) showed that words relating to actions involving a specific part of the body activate motor areas that control movements of that body part.

Current Status of Knowledge and Areas of Controversy

The converging neuropsychological and neuroimaging evidence has led to common agreement that semantic memory involves distributed brain networks. Conceptual knowledge of an object such as an 'apple' includes knowledge of its sensory properties (form, color, taste, smell, and tactile sensation) as well as the actions associated with it. The brain regions involved correspond (or at least overlap) with those involved in sensory perception and action (Martin, 2007; Pulvermüller, 2012). The implication is that object concepts are grounded in and emerge from weighted activity within property-based brain regions.

A principal area of contention is whether this distributed multimodal system (or systems) is sufficient to account for semantic knowledge. Proponents of the 'amodal semantics' view argue that it is not (Patterson et al., 2007). They reason that a primary function of the semantic system is to generalize across concepts that have similar significance, even though their sensory properties may be dissimilar. To do this requires a higher order amodal semantic representation that abstracts away from modality-specific attributes. The anterior temporal lobes have been proposed as a semantic hub, where information is distilled, permitting learning of conceptual relationships. The distinction between distributed multiple-modal and distributed + amodal hub views, delineated by Patterson et al. (2007), is illustrated in Figure 1.

There are good reasons for suspecting that the anterior temporal lobes may have a special role. Semantic dementia,

Figure 1 Two theoretical positions regarding the neuroanatomical distribution of the cortical semantic network and schematic models based on these views. which involves bilateral damage to anterior temporal lobes, is unique. No other disorder gives rise to such profound and pervasive semantic loss. Nevertheless, the temporal lobe degeneration is extensive leading to widespread loss of neural connectivity extending beyond anterior temporal regions. Moreover, even if crucial, it does not necessarily follow that the role of the anterior temporal lobes is in amodal representation. Antonio Damasio construed the anterior temporal lobes as areas of convergence, distinct convergence zones being dedicated to the association of different aspects of knowledge (Damasio et al., 2004). The finding of visual–verbal, right–left hemisphere differences in semantic dementia patients' recognition of famous faces and names would favor the notion of modality-specific convergence zones rather than a unitary amodal hub. The anterior temporal lobes might serve an integrative role, without entailing amodal representation. The precise site of a putative hub is unclear. Initially ascribed to the temporal pole, there is some neuroimaging evidence for a crucial role of anterior fusiform gyri (Mion et al., 2010). Visser et al. (2012) proposed two areas of convergence, one in middle temporal gyrus that integrates visual and auditory information and another in anterior temporal region identified as transmodal and interpreted as the core hub for coherent concepts.

The way that distributed information is integrated into coherent concepts is likely to remain a crucial area of research.

The Relationship between Semantic and Episodic Memory

Semantic dementia patients have impaired semantic knowledge and relatively preserved autobiographical memory, whereas classical amnesic patients show the reverse. Such clinical observations provide a persuasive argument for the utility of the distinction between semantic and episodic memory systems. Yet, does this necessarily mean that semantic and episodic memory systems are functionally independent? It would be reasonable to suspect that one might impact on the other. New semantic learning is indeed slowed in patients with episodic memory impairment, and performance on formal episodic memory tests is impaired in semantic dementia patients. This is unsurprising. It is harder to learn a list of words if they carry no meaning.

There are, however, additional findings that are less predictable and may seem counterintuitive (Snowden, 2002). In semantic dementia, the insidious loss of knowledge means that at any one stage of illness patients will know some things and not others. It is well established that factors such as frequency of occurrence, familiarity, and typicality are predictors of what is lost and retained. Thus, patients will understand 'dog' and 'horse' at a stage when they no longer recognize 'gnu' or 'bison.' Notwithstanding this general principle, semantic dementia patients who show an inability to name and comprehend simple terms such as pen and scissors may still generate surprisingly low-frequency vocabulary in conversation when it pertains to their own experience (e.g., "I attended the president's inauguration when I lived in Connecticut"; "I am church warden. I help prepare the chalice for the Eucharist"). Investigation of this phenomenon has shown a robust effect of personal familiarity (not equivalent to general frequency or familiarity of a word or object). Semantic dementia patients show superior recognition of names of people and places that have personal experiential relevance; they recognize their own objects better than alternative exemplars of the same object; they recognize objects better if they are in their usual location compared to a novel location. Importantly, their understanding of objects is influenced by their personal use, even if this is idiosyncratic. Thus, they may recognize a clothes peg as 'something used to close the breakfast cereal packet' and not as 'something used to hang clothes out to dry' if that is how they use clothes pegs in their daily lives. Patients' knowledge of the world appears to be increasingly narrow and personalized, linked to their own experience.

In Tulving's formulation, semantic memory was construed as information divorced from a temporospatial context. Yet, the findings in semantic dementia patients suggest their conceptual understanding of the world is very closely tied to their experiential autobiographical memories, including temporospatial context. Experiential memories support semantic knowledge. There is evidence too that semantic dementia patients are impaired in their ability to think prospectively about future events, reinforcing the notion of a functional interrelationship between semantic and episodic memory. Such findings suggest a more dynamic and interactive relationship between memory systems than often thought.

Future Directions in Semantic Memory Research

Much semantic memory research has centered on concrete words and objects. This is understandable not least because variables of interest can be readily manipulated and rigorously controlled. Yet, theoretical accounts must ultimately explain abstract as well as concrete concepts. They need to encompass affective as well as sensory properties of concepts. A narrow focus on semantic memory as a stable network of properties of words and objects may overlook a fundamental aspect of our knowledge: what we know comes from our experience. The precise nature of the interplay between semantic knowledge and autobiographical experience requires further exploration.

Do Schema Models Have a Role?

Schema approaches to semantic memory in the 1970s were motivated by the belief that study of word meanings alone cannot capture the richness and complexity of semantic knowledge. Patients with semantic dementia give cause to reflect again on this view. Such patients may, on occasion, generate a word appropriately in the context of spontaneous conversation (e.g., 'I'll put my shoes on'; 'I'll go and get my glasses'), yet in formal naming and word comprehension tests can neither name nor comprehend those nouns 'shoes' and 'glasses.' This apparent anomaly is not a reflection of performance variability. Semantic dementia patients are remarkably consistent in their performance, reflecting their degraded knowledge. If they cannot name or understand a word on one occasion, then they will be unable to do so on subsequent occasions. The findings point to the importance of another

factor: context. Patients may generate a word in the context of a propositional utterance, when they cannot do so in a standard naming task.

Putting on one's shoes or retrieving one's glasses constitutes a well-rehearsed goal-directed activity. So too is the verbal expression of intention to put on shoes or find one's glasses. It is possible that under conditions of profound degradation of semantic knowledge what are least vulnerable to disruption are the specific, well-rehearsed scripts of one's daily life. Experiential scripts might form the foundation upon which abstracted levels of meaning derive.

Concluding Remarks

The last decade has seen dramatic increase in the understanding of semantic memory. Patients with semantic memory disorders and sophisticated brain imaging paradigms have provided a window into the organization of semantic memory and its neural basis. However, there is still much to understand. Knowledge that London was the site of the 2012 Olympic Games is not readily divisible into sensory properties or motor actions. It is a reminder that semantic memory is more than an isolated set of word and object meanings: it is the wealth of experiential knowledge that enables us to function in the world around us.

Abstract

This article discusses the range of different approaches to capturing semantic similarity. Specifically, multidimensional scaling models and featural models (e.g., Tversky's contrast model) are introduced alongside newer approaches such as structural alignment accounts, context vectors, connectionist models, and generative probabilistic models. In addition, references are made to several cognitive abilities in which semantic similarity plays a role, including categorization, inductive reasoning, and memory.

Semantic similarity refers to similarity based on meaning as opposed to form. The term is used widely throughout cognitive psychology and related areas such as psycholinguistics, memory, reasoning, and neuropsychology. For example, semantically similar words are confusable with each other, and can prime each other, with the consequence that verbal memory performance is heavily dependent on similarity of meaning (*see* False Memories, Psychology of). In the context of reasoning, people draw inductive inferences on the basis of semantic similarity, for example, inferring that properties of cows are more likely to be true of horses than to be true of hedgehogs (Heit, 2000).

However, semantic similarity is not only central to psychology, it also plays an ever-increasing role in many practical computing contexts, particularly in the areas of natural language processing and information retrieval, making its study a more and more interdisciplinary endeavor.

But what is semantic similarity? In experimental work, semantic similarity is often estimated directly from participants' explicit judgments. However, there are several advantages to representing semantic similarity within a standardized framework or model. These advantages include the greater consistency and other known mathematical properties that can be imposed by a formal model, and the possible benefits of data reduction and the extraction of meaningful dimensions or features of the stimuli being analyzed. The history of research concerning semantic similarity can be captured in terms of the succession of models that have been applied to this topic. The models themselves can be divided into generic models of similarity and a number of more specialized models aimed at particular aspects of semantic similarity.

General Models of Similarity

Although the following accounts are meant to address similarity in general terms, they can be readily applied to semantic similarity. The two classical, generic approaches to modeling similarity are spatial models of similarity and Tversky's (1977) contrast model. More recently, structured approaches have addressed limitations of both of these classical accounts.

Spatial Representations

Spatial models seek to represent similarity in terms of distance in a psychological space (Shepard, 1980). An item's position is determined through its coordinate values along the relevant dimensions; nearby points thus represent similar items, whereas distant items are psychologically very different. For example, a spatial representation of mammal categories might represent different animals on dimensions of size and ferocity, with lions and tigers being close on both of these dimensions (**Figure 1**). The relevant space is derived using the technique of multidimensional scaling (MDS), a statistical procedure for dimensionality reduction. MDS works from experimental participants' judgments, typically in matrices of proximity data such as pairwise confusions or similarity ratings between items. Spatial models have been used widely for visualization purposes and as the heart of detailed cognitive models, e.g., of categorization and recognition memory (Nosofsky, 1991). Less widely used are related statistical procedures such as hierarchical

Figure 1 Multidimensional scaling representation of mammals.

clustering (Shepard, 1980), although they have also been used in the context of semantic similarity.

The Contrast Model

The traditional alternative to spatial models is Tversky's (1977) contrast model. This account was developed to address perceived limitations of spatial models, which bring these into conflict with behavioral data (but also see Nosofsky, 1991). Chief among these are violations of the so-called metric axioms that underlie any spatial scheme, such as asymmetries in human similarity judgments that are not well captured by spatial distance, which should be symmetrical. For example, people judged the similarity of North Korea to China to be greater than the similarity of China to North Korea. In the contrast model (eqn [1]), the similarity between items *a* and *b* is a positive function of the features common to both items and a negative function of the distinctive features of *a* and also the distinctive features of *b*. *Each of these three feature sets is* governed by a weighting parameter, which allows the model to capture asymmetries according to the nature of a particular task. According to the focusing hypothesis, greater attention is given to distinctive features of the first item in a comparison than of the second item, hence $\alpha > \beta$. When China is more familiar than North Korea, having more known distinctive features, then the similarity from China to North Korea should be lower than the similarity of North Korea to China:

$$S(a,b) = \theta f(A \cap B) - \alpha f(A - B) - \beta f(B - A) \qquad [1]$$

Although applications of the contrast model to the modeling of specific cognitive tasks are fewer than those of spatial models, an early application to semantic similarity can be found in Ortony (1979), who applied the model to distinctions between literal and metaphorical similarity.

Structured Representations

Despite the efforts aimed at establishing the superiority of either the contrast model or spatial models, it has been argued that both approaches share a fundamental limitation in that they define similarity based on oversimplified kinds of representations: points in space or feature sets. Arguably, most theories of the representation of natural objects, visual textures, sentences, etc. assume that these cannot be represented in line with these restrictions. Instead, they seem to require structured representations: complex representations of objects, their parts and properties, and the interrelationships between them. Descriptions such as SIBLING-OF (Linus, Lucy) and SIBLING-OF (Lucy, Linus) cannot be translated in an obvious way to either lists of features or points in space that represent the similarity between these two items as well as their differences from BROTHER-OF (Linus, Lucy). (See also Fodor and Pylyshyn (1988) for a critique of attempts in connectionist networks to represent relational structure in a featural framework.)

The perceived need for accounts of similarity to work with structured representations has given rise to the structural alignment account (see Markman (2001) for an overview), which has its roots in research on analogical reasoning. Structural alignment operates over structured representations such as frames (*see* Schemas, Frames, and Scripts in Cognitive Psychology) consisting of slots and fillers. The comparison process requires that at least some of the predicates, that is relations such as ABOVE (x, y) are identical across the comparison. These identical predicates are placed in correspondence. The alignment process then seeks to build maximal structurally consistent matches between the two representations.

Structural alignment has been implemented in a variety of computational models (e.g., Falkenhainer et al., 1990; Goldstone and Medin, 1994) that have been used to capture behavioral data, especially similarity judgments and analogical reasoning. Experimental results have supported an important prediction of the structural alignment account, that there will be a greater impact of alignable differences compared with nonalignable differences. Nonalignable differences between two representations are elements of one object that have no correspondence in the other. In contrast, alignable differences refer to representational elements that have corresponding roles in the two representations but fail to match exactly. For example, imagine two tables, one with a flower on top and the other with a bowl on top in addition to a chair beneath it. Comparing the two scenes, flower versus bowl would be an alignable difference, whereas the chair would be a nonalignable difference.

Transformational Accounts of Similarity

Most recent among the general approaches to similarity is the transformational account. This views the similarity between two objects as a function of transformation distance, that is, the complexity of transforming ones representation of one object into that of the other (e.g., Hahn et al., 2003). For example, the sequences 1 2 3 4 5 and 2 4 6 8 10 are comparatively similar because a simple operation ($\times 2$) suffices to convert the former into the latter, whereas the relationship between 1 2 3 4 5 and 3 5 7 9 11 is more complex ($\times 2 + 1$), giving rise to a greater distance, and hence, reduced similarity. This account generalizes featural or spatial accounts in as much as the addition, substitution, or deletion of features or shifts along continuous valued dimensions can be seen as particular types of transformations. However, a much broader class of transformations (such as, for example, those important in perceptual contexts such as object constancy like rotation, scaling, shear, etc.) are argued to be psychologically relevant, and this can lead to diverging predictions with featural or spatial models, because such transformations may naturally affect many stimulus aspects at once. In such cases, where a simple transformation gives rise to many individual changes at once, transformational accounts predict that items will be seen as similar, whereas featural or spatial models that track these individual changes will predict dissimilarity. Unlike featural and spatial models, the transformational account is also not restricted to particular types of representation, and measures of transformation distance can be defined both over simple feature lists (or continuous spaces), and over structured representations. Like the featural account, and in contrast to simple spatial models, the transformational account also allows asymmetric similarity. Transformations may be simpler in one direction than in the other, and there is experimental

evidence to suggest that asymmetric similarities may be created by priming directional transformations (Hahn et al., 2009).

Psychological research on transformations and similarity has – to date – focused on perceptual stimuli, but a number of specialized measures of semantic similarity can be conceptualized in transformational terms.

Specialized Models of Semantic Similarity

Semantic Differentials

Leaving behind generic models of similarity, semantic similarity has also been captured through a variety of specially built models and approaches. The first of these is Osgood et al.'s (1957) semantic differential. This approach used psychometric techniques to compute the psychological distance between concepts. Participants were required to rate concepts on 10–20 bipolar scales for a set of semantically relevant dimensions, such as positive–negative, feminine–masculine. The ratings of words on these dimensions would essentially form their coordinates in semantic space. The approach is thus related to spatial models of similarity with the difference primarily in the way that the semantic space is derived. Whereas models based on MDS require pairwise proximity data for all concepts of interest, the semantic differential approach requires that all concepts of interest are rated on all relevant dimensions. Therefore, the semantic differential method suffers from the difficulty that the relevant dimensions must be stipulated in advance. Still, semantic differentials have been widely used, largely because the data are straightforward to collect, analyze, and interpret.

Semantic Networks and Featural Models

The work of Osgood et al. motivated the semantic feature model of Smith et al. (1974) which addressed how people verify statements such as 'a robin is a bird' and 'a chicken is a bird,' considering the defining and characteristic features of these concepts. Verifying the latter statement would be slower owing to different characteristic features for chicken versus bird. The semantic feature model was developed in contrast to Collins and Quillian's (1969) semantic network model. In this model semantic meaning is captured by nodes that correspond to individual concepts. These nodes are connected by a variety of links representing the nature of the relationship between the nodes (such as an 'IS–A' link between robin and bird, indicating that a robin is a bird). Semantic similarity (or distance) is captured in terms of the number of links that must be traversed to reach one concept from another. Although the semantic network model was a groundbreaking attempt at capturing structured relations, it still suffered from some problems. For example, the model correctly predicts that verifying 'a robin is an animal' is slower than verifying 'a robin is a bird' owing to more links being traversed for the first statement. However, this model did not capture typicality effects such as the difference between robin and chicken.

While Collins and Quillian's (1969) model plays a largely historic role in psychology today, the concept of semantic networks and, more generally, graph-based representations of meaning, is very much alive in a variety of practical contexts. Computer scientists concerned with information retrieval, in particular in the context of the World Wide Web, routinely make use of ontologies represented in graph structures. Likewise computational linguists work frequently with graph-based lexical representations; chief among these is the widely used WordNet (see e.g., Miller, 1995; Fellbaum, 2005), a computer-based, large-scale, lexical database of English. WordNet contains nouns, verbs, adjectives, and adverbs in a thesaurus-like fashion, whereby words are grouped into sets of cognitive synonyms. These so-called 'Synsets' are then interlinked by conceptual semantic and lexical relations, such as IS–A links, and part–whole relations.

A variety of formal measures of similarity defined over graph structures have been proposed. Broadly, these measures can be classed as node- or edge (link)-based. The simple measure described in the context of Collins and Quillian's model (i.e., the number of links that need to traversed between two nodes) is a typical example of an edge-based measure. By contrast, node-based measures are based on the identification of common superordinate nodes for the two concepts (nodes) being compared. A prime example of this are so-called information content measures (e.g., Resnik, 1999). In the kinds of graph structures we are considering here, nodes represent unique concepts, which can be thought of as consisting of a certain amount of information. Given then that an edge represents some form of direct association between two concepts, one might view the similarity between two concepts as the extent to which they share information in common. One way of operationalizing this notion of shared information is by identifying it with common nodes further up in the hierarchy that subsume the two nodes in question. Typically, only the first superordinate node that subsumes both concepts is considered. The information content of a node (i.e., concept) is equated with its probability of occurrence, as estimated by its frequency within a large corpus of text. So the similarity between two concepts is then defined as the information content value of the first shared superordinate concept. Finally, hybrid measures combining node- and edge-based components have also been examined (e.g., Jiang and Conrath, 1997).

Though most of this research on graph-based measures of similarity has been conducted outside of psychology, putative measures of semantic similarity are routinely evaluated against benchmark human data sets such as those of Miller and Charles (1991). At the same time, the boundaries between disciplines are becoming increasingly blurred where large-scale models of semantic similarity are concerned, and popular graph-based measures can now also be found in recent research aimed specifically at psychological questions about semantic representation (see e.g., Johns and Jones, 2012).

High-Dimensional Context Spaces

Arguably the presently most popular approach to measuring semantic similarity within psychology is the use of context vectors. These corpus-derived measures of semantics and semantic similarity are successors to the idea of spatial representations of similarity. As an example, Burgess and Lund's (1997) hyperspace analog to language model (HAL) learns a high-dimensional context from large-scale linguistic corpora that encompass many millions of words of speech or text. The

model tracks lexical co-occurrences throughout the corpus and from these derives a high-dimensional representational space. The meaning of a word is conceived of as a vector. Each element of this vector corresponds to another word in the model, with the value of an element representing the number of times that the two words co-occurred within the discourse samples that constitute the corpus. For example, the vector for 'dog' will contain an element reflecting the number of times that the word 'bone' was found within a given range of words in the corpus. These vectors can be viewed as the coordinates of points (individual words) in a high-dimensional semantic space. Semantic similarity is then a matter of distance between points in this space. Several such usage-based models have been proposed to date: similar in spirit to HAL, for example, is Landauer and Dumais's (1997) Latent Semantic Analysis. Latent semantic analysis (LSA) is presently the most widely used of the usage-based models, last but not least, because the project website allows researchers to retrieve similarities between words from a simple user interface without the need to run the model themselves. LSA is also the most widely considered usage-based model in recent comparisons between competing approaches to semantic similarity (see the section Model Evaluation). The most recent addition to the family of context-based models, Jones and Mewhort's (2007) BEAGLE (for Bound Encoding of the Aggregate Language Environment) combines co-occurrence information with statistical information about transitions between words within a holographic memory system. Once again, words are represented by vectors based on patterns of use, but a lexical vector contains the superposition of both a word's context and order information across all the sentences in which it has been encountered. This gives a more fine-grained semantic representation. At the same time, the model seeks to provide a computationally more efficient, and hence psychologically more plausible approach to the acquisition of these representations.

The basic approach of co-occurrence-based models such as HAL, LSA, or BEAGLE takes to its logical consequence Wittgenstein's famous adage of 'meaning as use.' Its prime advantage over related approaches such as MDS-based spatial models of similarity and the semantic differential lies in the ability to derive semantics and thus measures of semantic similarity for arbitrarily large numbers of words without the need for any especially collected behavioral data. The ability of these models to capture a wide variety of phenomena, such as results in semantic priming and effects of semantic context on syntactic processing, has been impressive.

Generative Probabilistic Models

This approach to semantic similarity is, once again, fundamentally statistical in orientation. Like usage-based models, generative probabilistic models are derived from large corpora of text. They can be seen as probabilistic generalizations of usage-based models whereby texts within a corpus are construed as a probabilistic weighting over a set of discourse topics, and topics themselves correspond to probability distributions over words. Conversely, the distribution of words across topics can then be viewed as a representation of word meaning, and the semantic similarity between words is derived from comparison of these distributions across topics. The topics themselves are learned within a hierarchical Bayesian model (Blei et al., 2003; Griffiths et al., 2007). For example, the model may infer latent topic areas such as 'sport,' characterized by a high frequency of occurrence for words such as 'team,' 'play,' 'game,' and so on, or a topic such as 'legal system,' characterized by the frequent occurrence of words such as 'trial,' 'legal,' 'attorney,' and so on. These models are generative models in the sense that the selection of words found in the actual texts are seen as (probabilistically) generated from the underlying topics which the model has inferred. One advantage of topic models is that the generality of the underlying modeling framework allows them to combine readily semantic information with other sources of linguistic or perceptual knowledge.

Connectionist Approaches

The final approach to semantic similarity to be discussed shares with context-based models a statistical orientation, but connectionist modeling has been popular particularly in neuropsychological work on language and language processing. In connectionist models, the semantics of words are represented as patterns of activations, or banks of units representing individual semantic features. Semantic similarity is then simply the amount of overlap between different patterns; hence these models are related to the spatial accounts of similarity. However, the typically nonlinear activation functions used in these models allow virtually arbitrary re-representations of such basic similarities. The representation schemes utilized in these models tend to be handcrafted rather than derived empirically as in other schemes, such as MDS and high-dimensional context spaces. Frequently, they simply involve randomly generated representations; as demonstrated by Johns and Jones (2010), this may inadvertently influence model performance if the distributions of semantic similarities so generated do not match those associated with real words. However, it is often only very general properties of these semantic representations and the similarities between them that are crucial to a model's behavior, such as whether these representations are 'dense' (i.e., involve the activation of many semantic features) or 'sparse,' so that the actual semantic features chosen are not crucial. For example, this distinction between dense and sparse representation has been used to capture patterns of semantic errors associated with acquired reading disorders (Plaut and Shallice, 1993) and also patterns of category specific deficits following localized brain damage (Farah and McClelland, 1991). Rogers and McClelland (2004, 2008), in particular, have used simple connectionist models of semantic representation to explain a wide range of phenomena in conceptual development, as well as adult cognition in both typical and atypical adult populations, such as semantic dementia. The fact that insights from modeling have been linked to both neuropsychological and neuroimaging data (see Rogers et al., 2004; Patterson et al., 2007) means further that connectionist notions of semantic similarity have provided a bridge to the ever-increasing interest in semantic representation within cognitive neuroscience.

Model Evaluation

Models of semantic representation are routinely evaluated against human behavioral data. Chief among these are word association norms, priming data, and similarity ratings. Given the burgeoning interest both in semantic representation and semantic similarity, model evaluation increasingly also involves model comparisons. One difficulty here is that many of the models introduced above are very sensitive to parameterization. Bullinaria and Levy (2007), for example, show how factors such as the size of the training corpus or size of the context window affect model performance for usage-based models, and very simple measures may outperform more complex models when given sufficient amounts of training data (Recchia and Jones, 2009). This makes it difficult to obtain robust answers to the question of which model is 'better.' However, given the scale of these models, systematic exploration of relevant parameters is, at the very least, daunting.

This provides an impetus toward the comparative evaluation of more general model properties. Themes from the literature on general models of similarity thus recur within the context of specialized models of semantic similarity. Both the issue of structured representations, and potential violations of the metric axioms underlying spatial models have been raised in critiques of vector-based co-occurrence models such as LSA; for example, Griffiths et al. (2007) provide evidence that semantic similarity may be asymmetric. However, in the same way that proponents of MDS-based spatial models of similarity have sought to account for evidence of asymmetric similarities by appeal to characteristics of the processes (such as categorization) that draw on these similarities (e.g., Nosofsky, 1991), proponents of vector-based co-occurrence models have sought to show how asymmetries may arise naturally when the underlying vector space is coupled with a simple choice rule governing the actual task (Jones et al., 2011).

Computational complexity is another issue that has been highlighted in model comparisons (e.g., Recchia and Jones, 2009), and, now that the utility of distributional statistics in the context of semantics is well established, there is likely to be increased consideration of ways in which such information may efficiently be exploited in ways that are realistic given human information processing limitations.

Finally, models are being evaluated with respect to very general considerations about the nature of human semantic memory. The question of how best to measure or model semantic similarity is necessarily interlinked with the question of how semantic information is represented in the first place. While early accounts of semantic memory (Tulving, 1972) assumed amodal representations, there has been a wealth of research suggesting that semantic memory is experientially grounded and that semantic representations involve, or at least are linked with, representations of relevant sensorimotor experiences (see e.g., Barsalou, 2008). An early critique of usage-based models by Glenberg and Robertson (2000) focused on the fact that these models do not connect with perceptual experience. In contrast to featural models, which may include perceptual features in their representations of objects, context vectors do not connect directly with the world: knowing that 'dog' is similar to 'cat' in terms of patterns of linguistic co-occurrence is insufficient to allow one to identify either cats or dogs. Recently, modeling work such as Andrews et al. (2009) and Johns and Jones (2012) has tried to meet this challenge by showing how distributional information about context may be combined with perceptual information (features) leading to better predictions of semantic similarity.

Conclusion

There is a wide variety of models of semantic similarity available. Underlying this array of approaches is a classic tension that is as yet unresolved. Many of the models reviewed can be classed as loosely spatial in nature. These models have all been applied extensively to behavioral data; yet there are fundamental limitations to spatial approaches with respect to their representational capacity, made clear by the successes of the contrast model and the structural alignment approach. This leaves this area of research with two contrasting and seemingly incompatible strands of models, each of which successfully relates to data. One possibility for reconciliation is that spatial models and structured representations capture different aspects or types of semantic similarity: one automatic, precompiled, effortless, and in some ways shallow, and one the result of more in-depth, or line, or metacognitive processing. Such a distinction between types of processing of similarity would be compatible with the success of models based on, for example, context spaces in capturing phenomena such as semantic priming, and the success of models such as those based on structural alignment in capturing phenomena such as analogy, or the understanding of novel concept combinations. Whether such a distinction will take shape or whether there will one day be a single, all-encompassing account remains for future research. Further development of models of semantic similarity, however, will be able to benefit not only from computational ideas developed both within and outside psychology, but also from the explosion of interest in semantic representation and semantic similarity within cognitive neuroscience (see e.g., Binder et al., 2009 for a review).

Semantics

John I Saeed, Centre for Language and Communication Studies, Trinity College Dublin, Dublin, Ireland

Abstract

Semantics is the study of meaning communicated through language and is usually taken to be one of the three main branches of linguistics, along with *phonology*, the study of sound systems, and *grammar*, which includes the study of word structure (*morphology*) and of sentence structure (*syntax*). This article surveys some of the main topics of current semantics research.

Introduction

Traditionally, the main focus of linguistic semantics has been on word meaning, or lexical semantics. Since classical times writers have commented on the fact, noticed surely by most reflecting individuals, that the meaning of words changes over time. Such observations are the seeds of etymology, the study of the history of words. Over longer stretches of time, such changes become very obvious, especially in literate societies. Words seem to shift around: some narrow in meaning such as English *queen* which earlier mean 'woman, wife' but now means 'wife of a king.' Others become more general, while still others shift to take on new meaning or disappear altogether. Words are borrowed from language to language. The study of such processes is now part of historical semantics (Allan and Robinson, 2011). Another motivation for the study of word meaning comes from dictionary writers as they try to establish meaning correspondences between words in different languages, or in monolingual dictionaries, seek to provide definitions for all the words of a language in terms of a simple core vocabulary. In lexicology, similarities and differences in word meaning are a central concern.

The principled study of the meaning of phrases and sentences has only become established in linguistics relatively recently. Thus it is still common for descriptive grammars of individual languages to contain no separate section on semantics other than providing a lexicon. Nonetheless it has always been clear that one can identify semantic relations between sentences. Speakers of English know from the semantics of negation that nominal negation has different effects than sentence negation, so that *No-one complained* may aptly be used to answer *Who complained?* while *Someone did not complain* may not. Two other sentences may seem to say essentially the same thing, even be paraphrases of each other, yet one may be more suited to one context than another, like the pair *Bandits looted the train* and *The train was looted by bandits*. A single sentence may be internally inconsistent such as *Today is now tomorrow* or seem to be repetitive or redundant in meaning such as *A capital city is a capital city*. Another feature of sentence meaning is the regularity with which listeners draw inferences from sentences and often take these to be part of the meaning of what was said. Some inferential links are very strong, such as entailment. Thus we say that *Bob drank all of the beer* entails *Bob drank some of the beer* (assuming the same individual Bob, beer, etc.), because it is hard to think of a situation where acceptance of the second sentence would not follow automatically from acceptance of the first. Other inferential links are weaker and more contextually dependent: from the utterance *Bob drank some of the beer* it might be reasonable to infer *Bob didn't drink all of the beer* but it is possible to think of situations where this inference would not hold. We might say that a speaker of the first sentence is implying the second, in a certain context. Speakers of all languages regularly predict and use such inferential behavior to convey their meaning, such that often more meaning seems to be communicated than is explicitly stated. All these aspects of sentence meaning and are currently under study in various semantic frameworks.

Semanticists share with philosophers an interest in key issues in the use of language, notably in reference. We use this term to describe the way in which speakers can pick out, or name, entities in the world by using words as symbols. Many scholars, especially formal semanticists, accept Frege's distinction between reference (in German, *Bedeutung*) and sense (*Sinn*); see Frege (1980). Reference is the act of identifying an entity (the referent) while sense is the means of doing so. Two different linguistic expressions like *the number after nine* and *the number before eleven* differ in sense but they both share the same referent, *ten*. For semanticists it is particularly interesting to study the various mechanisms that a language offers to speakers for this act of referring. These include names like *Dublin*, nouns like *cat* which can be used to refer to a single individual *your cat* or a whole class *Cats are carnivorous*, quantified nominals like *many cats*, *some cats*, *a few cats*, etc. and so on. Linguists as well as philosophers have to account for language's ability to allow us to refer to nonexistent and hypothetical referents like *World War Three*, *the still undiscovered cure for cancer*, *the end of the world*.

Semanticists also share interests with psychologists, for if sense is the meaning of an expression, it seems natural to many semanticists to equate it with a conceptual representation. Cognitive linguists in particular (for example, Talmy, 2000; Langacker, 2008), but also some generative linguists (Jackendoff, 2002), seek to explore the relationship between semantic structure and conceptual structure. One axis of the debate is whether words, for example, are simply labels for concepts, or whether there is a need for an independent semantic interface that isolates just grammatically relevant elements of conceptual structure. Many languages make grammatical distinctions corresponding to the conceptual distinctions of gender and number but few involve distinctions of color or between different animal species. If certain aspects of concepts are more relevant to grammatical rules, as is also claimed by Pinker (1989), this may be justification for a semantic interface.

Approaches to Meaning

Even in these brief remarks we have had to touch on the crucial relationship between meaning and context. Language of course typically occurs in acts of communication and linguists have to cope with the fact that utterances of the same words may communicate different meanings to different individuals in different contexts. One response to this problem is to hypothesize that linguistic units like words, phrases, and sentences have an element of inherent meaning that does not vary across contexts. This is sometimes called inherent, or simply, sentence meaning. Language users, for example, speakers and listeners, then enrich this sentence meaning with contextual information to create the particular meaning the speaker means to convey at the specific time, which can then be called speaker meaning. One common way of reflecting this view is to divide the study of meaning into semantics, which becomes the study of sentence meaning, and pragmatics, which is then the study of speaker meaning, or how speakers use language in concrete situations. This is an attempt to deal with the tension between the relative predictability of language between fellow speakers and the great variability of individual interpretations in interactive contexts. One consequence of this approach is the view that the words that a speaker utters underdetermine her intended meaning.

Semantics as a branch of linguistics is marked by the theoretical fragmentation of the field as a whole. The distinction between formal and functional approaches, for example, is as marked in semantics as elsewhere. This is a large subject to broach here but see Givón (1995) and Newmeyer (1998) for characteristic and somewhat antagonistic views, though Newmeyer (2010) strikes a conciliatory note. One important difference is the attitude to the autonomy of levels of analysis. Are semantics and syntax best treated as autonomous areas of study, each with its own characteristic entities and processes? A related question at a more general level is whether linguistic processes can be described independently of general psychological processes or the study of social interaction. Scholars in different theoretical frameworks will give contradictory answers to these questions of micro- and macro-autonomy. Autonomy at both levels is characteristic of semantics within generative grammar (see, for example, Chomsky, 1995). Functionalists like Halliday (1994) and Harder (1996) would on the other hand argue against micro-autonomy, suggesting that grammatical relations and structure cannot be understood without reference to semantic function. They also seek motivation for linguistic structure in the dynamics of communicative interaction. A slightly different external mapping is characteristic of cognitive semantics (for example, Langacker, 2008), where semantic structures are correlated to conceptual structures.

Another dividing issue in semantics is the value of formal representations. Scholars are divided on whether our knowledge of semantics is sufficiently mature to support attempts at mathematical or other symbolic modeling, indeed on whether such modeling serves any use in this area. Partee (2004), for example, defends the view of formal semanticists that the application of symbolic logic to natural languages, following in particular the work of Montague (1974), represents a great advance in semantic description. Jackendoff (2002) on the other hand acknowledges the value of formalism in semantic theory and description but argues that formal logic is too narrow to adequately describe meaning in language. Other scholars, such as Wierzbicka (1996) and Goddard (2008), view the search for formalism as premature and distracting.

There has been an explosive increase in the research in formal semantics since Montague's (1974) proposal that the analysis of formal languages could serve as the basis for the description of natural languages. Montague's original theory comprised a syntax for the natural language, say English, a syntax for the logical language into which English should be translated (intensional logic), rules for the translation, and rules for the semantic interpretation of the intensional logic. This and subsequent formal approaches are typically referential (or denotational) in that their emphasis is on the connection of language with a set of possible worlds, including the real, external world and the hypothetical worlds set up by speakers. Crucial to this correspondence is the notion of truth, defined at the sentence level. A sentence is true if it correctly describes a situation in some world. In this view, the meaning of a sentence is characterized by describing the conditions which must hold for it to be true. The central task for such approaches is to extend the formal language to cope with the semantic features of natural language while maintaining the rigor and precision of the methodology (see van Benthem and Ter Meulen, 2010 for a comprehensive overview of research in this paradigm).

Research in cognitive semantics presents an alternative strategy. Cognitive semanticists reject what they see as the mathematical, anti-mentalist approach of formal semantics. In their view, meaning is described by relating linguistic expressions to mental entities, conventionalized conceptual structures. These semanticists have proposed a number of conceptual structures and processes, many deriving from perception and bodily experience and in particular, conceptual models of space. Proposals for underlying conceptual structures include image schemas (Johnson, 1987), mental spaces (Fauconnier, 1997), and conceptual spaces (Gärdenfors, 1999). Cognitive semanticists are sympathetic to usage-based accounts such as Taylor (2012), which relates linguistic representations to stored memories of actual language events. Another focus of interest is the processes for extending concepts and here special attention is given to metaphor. Lakoff (1987) and Johnson (1987) have argued against the classical view of metaphor and metonymy as something outside normal language, added as a kind of stylistic ornament. For these writers metaphor is an essential element in our categorization of the world and our thinking processes. Cognitive semanticists have also investigated the conceptual processes which reveal the importance of the speaker's perspective and construal of a scene, including viewpoint shifting, figure-ground shifting, and profiling (Langacker, 2008).

Topics in Sentence Semantics

Many of the semantic systems of language, for example, tense, aspect, mood, and negation, are marked grammatically on individual words such as verbs. However, they operate over the whole sentence. This 'localization' is the reason that

descriptive grammars usually distribute semantic description over their analyses of grammatical forms. Such semantic systems offer the speaker a range of meaning distinctions through which to communicate a message. Theoretical semanticists attempt to characterize each system *qua* system, as in, for example, Verkuyl's (1993) work on aspect and Hornstein's (1990) on tense. Typological linguists try to characterize the variation in such systems across the world's languages, as in the studies of tense, aspect, and mood by Comrie (1976, 1985), Binnick (1991), Bybee et al. (1994), Dähl (1985, 2000), and Frawley (2006). We can sketch some basic features of some of these systems.

Tense

Tense is the linguistic marking of time and allows a speaker to locate a described situation relative to some reference point in time. The basic reference point is the time of speaking or writing. Tense is thus described as a deictic system since it is part of a language's system for establishing spatial, temporal, and human zones of reference around the speaker. For example, in English the deictic words *here*, *now*, *I*, *you* provide points of reference, the contents of which are establishing within a particular context of communication. Tense is often associated with verbs but may be marked by other elements, even in English where temporal adverbs may carry a similar function, as in the contrast between *We let the apartment last year*, *We let the apartment every year*, *We let the apartment next week*. Most grammatical tense systems allow the speaker to describe situations as prior to, concurrent with, or following the act of speaking. So in English, we have the three tenses: past, future, and present. These are basic tenses, usually marked on a verb and can be represented by a diagram like **Figure 1** (using *understand* as an example), in which time is metaphorically represented as line moving left to right, and the symbol represents the time of the act of speaking or writing.

When events are located by tenses in this way against the act of speaking, they are termed absolute tenses. More complicated time references are built on this simple system. By using complex tenses in English, for example, a speaker can identify a time in the past or future and use that time as the reference point for an event in its own past or future, as in examples like *By last Friday he had interviewed seven candidates*, or *Before the end of this century we will have discovered a cure for cancer*. These are often called relative tenses since they are parasitic on the basic system. Such a subdivision of the past or future can be represented in a simple diagram like **Figure 2** where represents the extra reference point in time.

Reichenbach (1947) proposed a system for describing these absolute and relative tense possibilities. In it the time of the act of speaking (or utterance time) is termed S and the time of the

Figure 1 Simple tenses.

Figure 2 Complex past tense in *By last Friday he had interviewed seven candidates*.

described event, E. Thus present tense has the two overlapping, written S, R, while the other simple tenses involve a precedence, shown as E_S for the past and S_E for the future. As we have seen, the complex tenses require an extra reference point other than S, called in this system the reference time, R. In simple tenses R is simultaneous with E but in complex tenses R may be before or after E. So in **Figure 2** the event (the interview) occurs before the reference time (last Friday) and the reference time occurs before the act of speaking. These relations can be represented as (E_R) and (R_S), which then describes the past perfect in English. Reichenbach's system is developed further in Klein (1994) (see Comrie, 1985; Hornstein, 1990 for discussion of this system to describe the range of tenses found in languages).

The marking of temporal reference by tense is usually supported in real-life communication by pragmatic inferences. Wilson and Sperber (2012b) discuss how temporal ordering or sequencing is often inferred in context, for example, in deciding whether the clauses in *John left and Joan got angry* are to be taken as sequential. Similarly, intervals of time are often unspecified and left to be inferred in context as in the possible time intervals inferred for their examples *I have had breakfast* and *I have been to Tibet*.

Situation Type and Aspect

Situation type and aspect are terms for a language's resources that allow a speaker to describe the temporal 'shape' of events. The term situation type is used to describe the system encoded in the words of a language, while aspect is used for the grammatical systems which perform a similar role. Distinctions of situation type, for which the term Aktionsart is also used, typically allow speakers to describe a situation either as static as in *The bananas are ripe* or as dynamic as in *The bananas are ripening*. Here the state is the result of the process but the same situation can be viewed as more static or dynamic as in *The baby is asleep* and *The baby is sleeping*. As these examples show, this distinction is lexically marked: in English, for example, adjectives are typically used for states and verbs for dynamic situations. There are, however, a group of stative verbs such as *know*, *understand*, *love*, *hate*, which describe static situation types. There are a number of semantic distinctions typically found amongst dynamic verbs, for example, the telic/atelic (bounded/unbounded) distinction and the punctual/durative distinction. Telic verbs describe processes which are seen as having a natural completion, which atelic verbs do not. A telic example is *Matthew was growing up* and an atelic, *Matthew was drinking*. If these processes are interrupted at any point we can automatically say *Matthew drank* but not *Matthew grew up*.

However atelic verbs can form telic phrases and sentences by combining with other grammatical elements so that *Matthew was drinking a pint of beer* is telic. Durative verbs, as the term suggests, describe processes that last for a period of time while punctual describes those that seem so instantaneous that it has no detectable internal structure, as in the comparison between *The man slept* and *The light flashed*. As has often been observed, if an English punctual verb is used with a durative adverbial, the result is an iterative meaning, as in *The light flashed all night*, where we understand the event to be repeated over the time mentioned.

Situation type typically interacts with aspect. Aspect is the grammatical system that allows the speaker choices in how to portray the internal temporal nature of a situation. An event, for example, may be viewed as closed and completed, as in *Joan wrote a book* or as an ongoing process, perhaps unfinished, as in *Joan was writing a book*.

The latter verb form is described as being in the progressive aspect in English but similar distinctions are very common in the languages of the world. In many languages we find described a distinction between perfective and imperfective aspects, used to describe complete versus incomplete events; see Bybee et al. (1994) for a survey. As mentioned above, aspect is intimately associated both with situation type and with tense. In Classical Arabic the perfective is strongly associated with past tense (Comrie, 1976; Binnick, 1991), while in Russian the imperfective is used to describe future events. In English, for example, stative verbs are typically not used with progressive aspect, so that one may say *I know some French* but not *I am knowing some French*. Staying with the progressive, when it is used in the present tense in English (and in many other languages) it carries a meaning of proximate future or confident prediction as in *We're driving to Los Angeles* or *I'm leaving you*. The combination of the three semantic categories of tense, situation type, and aspect produces a complex system that allows speakers to make subtle distinctions in relating an event or describing a situation.

Modality

Modality is a semantic system that allows speakers to express varying attitudes to a proposition. Semanticists have traditionally identified two types of modality. One is termed epistemic modality, which encodes a speaker's commitment to, or belief in, a proposition, from the certainty of *The ozone layer is shrinking* to the weaker commitments of *The ozone layer may/might/could be shrinking*. The second is deontic modality, where the speaker signals a judgment toward social factors of obligation, responsibility, and permission, as in the various interpretations of *You must/can/may/ought to borrow this book*. These examples show that similar markers, here auxiliary verbs, can be used for both types. When modality distinctions are marked by particular verbal forms, these are traditionally called moods. Thus many languages, including Classical Greek and Somali, have a verb form labeled the optative mood for expressing wishes and desires. Other markers of modality in English include verbs of propositional attitude as in *I know/believe/think/doubt/that the ozone layer is shrinking* and modal adjectives as in *It is certain/probable/likely/possible that the ozone layer is shrinking*.

A related semantic system is evidentiality, where a speaker communicates the basis or source for presenting a proposition. In English and many other languages this may be done by adding expressions like *allegedly, so I've heard, they say*, etc. but certain languages mark such differences morphologically, as in Makah, a Nootkan language spoken in Washington State (Jacobsen, 1986, 10):

Wiki•caxaw	'It's bad weather' (seen or experienced directly)
Wiki•caxakpi•d	'It looks like bad weather' (inference from physical evidence)
Wiki•caxakqadi	'It sounds like bad weather' (on the evidence of hearing)
Wiki•caxakwa•d	'I'm told there's bad weather' (quoting someone else)

Aikhenvald (2004) surveys such evidential systems across the languages of the world.

Semantic Roles

This term describes the speaker's semantic repertoire when deciding how to relate participants in a described event. One influential proposal in the semantics literature is that each language contains a set of semantic roles, the choice of which is partly determined by the lexical semantics of the verb selected by the speaker. A characteristic list of such roles is:

AGENT:	Initiator of some action, typically capable of acting with volition
PATIENT:	Entity undergoing the effect of some action, typically undergoing a change of state
THEME:	The entity which is moved by an action, or whose location is described
EXPERIENCER:	An entity aware of the action or state described by the predicate but not in control of it
RECIPIENT:	The entity which receives something
BENEFICIARY:	The entity benefiting from some action
INSTRUMENT:	The means by which an AGENT causes something to come about
LOCATION:	The place in which something is situated or takes place
GOAL:	The entity toward which something moves
SOURCE:	The entity from which something moves
STIMULUS:	The entity causing an effect in the EXPERIENCER

In an example like *Harry immobilized the tank with a broomstick*, the entity Harry is described as the AGENT, the tank as the PATIENT, and the broomstick as the INSTRUMENT.

These roles have also variously been called deep semantic cases, thematic relations, participant roles, and thematic roles.

One concern is to explain the matching between semantic roles and grammatical relations. In many languages, as in the last example, there is a tendency for the subject of the sentence to correspond to the AGENT, the direct object to a PATIENT or THEME, and an INSTRUMENT often occurs as a prepositional phrase. Certain verbs allow variations from this basic mapping, for example, the pattern we find with English verbs like *break*: *The boy broke the window with a stone* (Subject = AGENT), *The stone*

broke the window (Subject = INSTRUMENT), *The window broke* (Subject = PATIENT). Clearly verbs can be arranged into classes depending on the variations of mappings they allow and not all English verbs pattern like *break*. We can say *The admiral watched the battle with a telescope* but *The telescope watched the battle* and *The battle watched* sound decidedly odd.

From this literature emerges the claim that certain mappings are more natural or universal. One proposal is that, for example, there is an implicational hierarchy governing the mapping to subject, typically such as: AGENT > EXPERIENCER > THEME/PATIENT > INSTRUMENT > LOCATION. In such a hierarchy, each left element is more preferred than its right neighbor, so that moving rightward along the string gives us less expected subjects. The hierarchy also makes certain typological claims: if a language allows a certain semantic role to be the subject, it will allow all those to its left. Thus, if we find that a language allows the role INSTRUMENT to be the subject, we predict that it allows the roles to the left, but we do not know if it allows LOCATION subjects.

One further application of semantic roles is in lexical semantics where the notion allows verbs to be classified by their semantic argument structure. Verbs are assigned semantic role templates or grids by which they may be sorted into natural classes. Thus, English has a class of transfer, or giving verbs which in one type includes the verbs *give, lend, supply, pay, donate, contribute*. These verbs encode a view of the transfer from the perspective of the AGENT and may be assigned the grid <AGENT, THEME, RECIPIENT>, where the underlined argument is realized as the subject, as in *The committee donated aid to the famine victims*. A second subclass of these transfer verbs encodes the process from the perspective of the RECIPIENT. These verbs include *receive, accept, borrow, buy, purchase, rent, hire* and have the grid <RECIPIENT, THEME, SOURCE>, as in *The victims received aid from the committee*.

Entailment, Presupposition, and Implication

These terms relate to types of information a hearer gains from an utterance but which are not stated directly by the speaker. These phenomena have received a lot of attention because they seem to straddle the putative divide between semantics and pragmatics described above and because they reveal the dynamic and interactive nature of understanding the meaning of utterances. Entailment describes a relationship between sentences such that on the basis of one sentence, a hearer will accept a second, unstated sentence purely on the basis of the meaning of the first. Thus sentence A entails sentence B if it is not possible to accept A but reject B. In this view, a sentence like *I bought a dog today* entails *I bought an animal today*; or *President Kennedy was assassinated yesterday* entails *President Kennedy is now dead*. Clearly these sentential relations depend on lexical relations: a speaker who understand the meaning of the English word *dog* knows that a dog is an animal; similarly the verb *assassinate* necessarily involves the death of the unfortunate object argument. Entailment then is seen as a purely automatic process, involving no reasoning or deduction, but following from the hearer's linguistic knowledge. Entailment is amenable to characterization by truth conditions. A sentence is said to entail another if the truth of the first guarantees the truth of the second and the falsity of the second guarantees the falsity of the first.

Presupposition, on the other hand, is a more difficult notion. In basic terms the idea is simple enough: that a speaker communicates certain assumptions aside from the main message. A range of linguistic elements communicates these assumptions. Some, such as names, and definiteness markers, like the articles *the* and *my*, presuppose the existence of entities. Thus *James Brown is in town* presupposes the existence of a person so called. Other elements have more specific presuppositions. A verb like *stop* presupposes a preexisting situation. So a sentence *Christopher has stopped smoking* presupposes *Christopher smoked*. If treated as a truth conditional relation, presupposition is distinguished from entailment by the fact that the former but not the latter survives under negation: *Christopher has not stopped smoking* still presupposes *Christopher smoked* but the sentence *I didn't buy a dog today* does not entail *I bought an animal today*.

There are a number of other differences between entailment and presupposition that cast doubts on the ability of a purely semantic, truth conditional account of the latter. Presuppositions are notoriously context sensitive, for example. They may be canceled without causing an anomaly: a hearer can reply *Christopher hasn't stopped smoking, because he never smoked* to cancel the presupposition by what is sometimes called metalinguistic negation. This dependency on context has led some writers to propose that presupposition is a pragmatic notion, definable in terms of the set of background assumption that the speaker assumes is shared in the conversation (see Beaver, 1997 for discussion).

A third type of inference is Grice's conversational implicature (1975, 1978). This is an extremely context-sensitive type of inference which allows participants in a conversation to maintain coherence. So given the invented exchange below:

A: Did you give Mary the book?
B: I haven't seen her yet.

it is reasonable for A to infer the answer 'no' to her question. Grice proposed that such inferences are routinely relied on by both speakers and hearers and that this reliance is based on certain assumptions that hearers make about a speaker's conduct. Grice classified these into several different types, giving rise to different types of inference, or from the speaker's point of view, what he termed implicatures. The four main maxims are called Quality, Quantity, Relevance, and Manner (Grice, 1975, 1978). They amount to a claim that a listener will assume, unless there is evidence to the contrary, that a speaker will have calculated her utterance along a number of parameters: she will tell the truth, try to estimate what her audience knows and package her material accordingly, have some idea of the current topic, and give some thought to her audience being able to understand her. In our example above, it is A's assumption that B's reply is intended to be relevant that allows the inference 'no.'

Implicature has three characteristics: firstly, that it is implied rather than said; secondly, that its existence is a result of the context, i.e., the specific interaction. There is no guarantee that in other contexts *I haven't seen her* will be used to communicate *no*. Thirdly, implicature is cancellable without

causing a contradiction. Thus the implicature 'no' in our example can be canceled if B adds the clause *but I posted it to her last week*.

These three notions entailment, presupposition, and implicature can all be seen as types of inference. They are all produced in conversation and are taken by participants to be part of the meaning of what a speaker has said. They differ in a number of features and crucially in context sensitivity. The attempt to provide a unified analysis of them all is currently a challenge to semantic and pragmatic theories (see Wilson and Sperber, 2012a for discussion of such a unified approach).

Future Developments

Although semantics remains theoretically a very diverse field it is possible to detect some shared trends which seem likely to develop further. One is a move away from a static view of sentences in isolation, detached from the speaker/writer's act of communication toward dynamic, discourse-based approaches. This has always been characteristic of functional approaches to meaning but has also been noticeable in formal approaches as they move away from their more philosophical origins. Among prom-inent examples of this we might mention Discourse Representation Theory (Kamp et al., 2011) and Dynamic Semantics (Groenendijk et al., 1996). This move has put further pressure on decisions about the border to be drawn between semantics and pragmatics and in particular about semantic underspecification (see Recanati, 2004; Cappelen and Lepore, 2005; Preyer and Peter, 2005 for characteristic discussions).

Another development which seems likely to continue is a closer integration with other disciplines in cognitive science. In particular, computational techniques seem certain to make further impact on a range of semantic enquiry, from lexicography to the modeling of questions and other forms of dialogue. A subfield of computational semantics has emerged and will continue to develop (see van Eijck and Unger, 2010 for example).

Semiotics

Klaus B Jensen, University of Copenhagen, Copenhagen, Denmark

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Semiotics is the interdisciplinary study of signs, particularly their social origins, uses, and consequences. Rooted in philosophy, logic, and linguistics, the field has developed since the 1960s as an internationally influential approach to research on contemporary culture and communication. Revisiting classic epistemological issues, semiotics further has contributed to the theory of science by clarifying the relationship of a third form of inference – abduction – to deduction and induction. In the context of digital networks, semiotics helps to specify the several different categories of signs that enter into computer-mediated social interaction.

Semiotics is an interdisciplinary field that studies "the life of signs within society" (Saussure, 1959/1916: 16). While the term 'signs' is most commonly used to refer to the constituents of verbal language and other concrete vehicles of communication, in semiotics it further denotes any means of knowing about or representing some aspect of reality – through perception, cognition, or social interaction. Accordingly, semiotics exhibits a variety of family resemblances with disciplines such as philosophy, psychology, and sociology. From the 1960s, semiotics became an internationally influential approach to research on culture and communication within the humanities and social sciences. This article describes the classical origins of semiotics, exemplifies its applications to contemporary society, outlines its implications for the theory of science, and, in conclusion, considers an extension and potential redefinition of semiotics in the context of digital computers.

Origins: Logic and Linguistics

A Classical Heritage

One of the first accounts in Western philosophy and science of signs and their functions in representation and communication was advanced by Aristotle in the fourth century BCE:

> Spoken words are the symbols of mental experience and written words are the symbols of spoken words. Just as all men have not the same writing, so all men have not the same speech sounds, but the mental experiences, which these directly symbolize, are the same for all, as also are those things of which our experiences are the images.
>
> Aristotle, 2007: n.p.

Aristotle identified the minimal elements of most theories of knowledge, classical as well as modern: things in the world, mental impressions, and oral or written expressions about the things as well as the impressions. These elements – their status and interrelations – have preoccupied philosophy, and have continued to challenge natural, human, and social sciences. At issue has been the existence of a shared reality, the historical and cultural variability of human experience, and the relationship between subject and object, and between subject and subject, as mediated by signs, in some sense of that word.

Aristotle had suggested two main senses. First, the mental impressions that individuals hold could be considered signs that represent certain phenomena in the world to them. Second, spoken and written expressions are signs through which people are able to represent and communicate a particular understanding of these phenomena to others. The first sense – mental impressions – recalls a classical understanding of signs, not as words or images, but as naturally occurring evidence that something is the case. For example, fever is a sign of illness, and clouds are a sign that it may rain, insofar as these signs are interpreted by humans. The second sense – means of communication – points to the distinction that came to inform modern sciences between conventional signs, whether verbal language or mathematical notations, and natural signs or sense data.

An undercurrent in the history of ideas has addressed the ambiguities that follow from these several conceptions of what is a sign. A specific statement concerning natural signs and language as two varieties of one general category of signs was presented by St. Augustine (*c.*400 CE). Grounded in Christian cosmology of the medieval period, this view was elaborated with reference to an understanding of nature as God's Book and as an analogy to the Bible, or the Good Book. Both verbal and natural signs could be seen to bear witness to a divinely sanctioned order or 'great chain of being.' During the seventeenth century, the term 'semiotic,' along with a modern and more differentiated conception of signs, first appeared in John Locke's *An Essay Concerning Human Understanding* (1690). While proposing a science of signs in general, Locke, in fact, restricted his focus to "the most usual" signs (Clarke, 1990: 40), namely, verbal language and logic. Linguistics and logic became the two main disciplines feeding into contemporary semiotics, as represented by two founding figures: Ferdinand de Saussure and Charles Sanders Peirce.

Peircean Logic and Semiotics

Charles Sanders Peirce (1839–1914) was the first thinker to recover this undercurrent from the history of ideas in an attempt to develop a general semiotics, which he referred to as 'semeiotic' (for key texts, see Peirce, 1992–98). Peirce understood his theory of signs as a form of logic, which would inform a comprehensive philosophical system examining the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.95033-5

nature of both being (ontology) and knowledge (epistemology). The key to this system is Peirce's definition of the sign in terms of its three aspects:

> A sign, or *representamen*, is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign which it creates I call the *interpretant* of the first sign. That sign stands for something, its *object*.
>
> Peirce, 1931–58: 2.228

One important implication of this definition is that signs always serve to mediate between objects in the world (material and nonmaterial) and concepts in the mind. In contrast to skepticist positions from Antiquity to postmodernism, Peirce's point was that signs are not *what* we know, or all that we know, but *how* we come to know what we can justify saying that we know, in science as well as in everyday life. Peircean semiotics, thus, married a classical, Aristotelian notion of realism with the modern, Kantian position that humans necessarily construct their understanding of reality in particular cognitive categories.

Peirce further emphasized that human understanding is not a singular act of internalizing reality, but a continuous process of interpreting reality with a view to action, what he called 'semiosis.' This multistep process is witnessed, for example, in scientific discovery, but also in the continuous coordination of everyday life. Figure 1 illustrates the process of semiosis, indicating how any given interpretation (interpretant) itself serves as a sign in the next stage of a process that gradually differentiates the interpreter's understanding of objects in reality, and which, in principle, is unending. Although Peirce's outlook was that of a logician and a natural scientist, semiosis can be taken to also refer to those processes of communication by which cultures are maintained and societies reproduced and, to a degree, reformed.

Figure 1 The process of semiosis.

One of the most influential elements of Peirce's semiotics outside logic and philosophy has been his categorization of different types of signs, particularly icon, index, and symbol. Icons relate to their objects through resemblance (e.g., a realistic painting); indices have a causal relation (e.g., the sound of a drum beating); and symbols have an arbitrary relation to their object (e.g., the words of this article). Importantly, signs as actually used by humans in social contexts typically incorporate all of these three aspects to varying degrees. A photograph resembles what it depicts; it results from the impact of physical reality on a recording device; and it commonly symbolizes something beyond the immediate depiction, for instance, in advertising. Different disciplines and fields have employed these sign types as analytical instruments in order to describe the ways in which humans perceive, represent, and act in and on social reality.

In an interdisciplinary perspective, the relationship between semiosis and social action is key. Peirce was a founder not just of semiotics, but of pragmatism, as well, together with William James, John Dewey, and other thinkers. Semiosis informs beliefs, which anticipate actions. Along with semiotics, pragmatism has proven a central legacy for social sciences and cultural studies in recent decades (Dickstein, 1998).

Saussurean Linguistics and Semiology

The other main figure in the development of semiotics, Ferdinand de Saussure (1857–1913), focused on verbal language, which Peirce had described as belonging to one type of signs, namely symbols. The main achievement of Saussure was to outline a framework for modern linguistics. In contrast to the emphasis that philology had placed on the diachronic perspective of how languages change over time, Saussure proposed to study language as a system in a synchronic perspective. Language as an abstract system (*langue*) could be distinguished, at least for analytical purposes, from the actual uses of language (*parole*). The language system, according to Saussure, has two dimensions. Along the syntagmatic dimension, letters, words, phrases, etc., combine to make up meaningful wholes, and each of these units has been chosen as one of several possibilities along a paradigmatic dimension, for example, the verb 'choose' instead of 'select.' This combinatorial system helps to account for the unique flexibility of language as a medium of social interaction.

The intersection of the paradigmatic and syntagmatic axes gives rise to two wider forms of expression and representation – metaphor and metonymy – not just in literature, but in communication and culture generally. Metaphor is the outcome of an unexpected paradigmatic choice that affects the content of the communication as a whole (the syntagm) and, thus, activates additional frames of interpretation. For example, during the 1980s, the American politician and civil rights activist, Jesse Jackson, served as the spokesperson for a 'rainbow coalition'

that aimed to join various disempowered groups, particularly non-white communities, into a new political force. This term represents a significant contrast to the traditional reference to the US population as entering into a 'melting pot.' While the melting pot eliminates variety, the rainbow derives its essential quality and beauty from the difference and complementarity of multiple colors. Speeches and other communications would activate these meanings for a particular political purpose. Metonymy, in turn, is the process by which a single sign evokes the full syntagm to which that sign belongs. When 'the White House' was said to comment on the 'rainbow coalition,' the reference to the building would reference both the American presidency and the authority and vested interests associated with it (Drotner et al., 1996: 195).

To be precise, Saussure referred to the broader science of signs, as cited in the introduction to this article, not as semiotics, but as 'semiology.' Like Locke, and later Peirce, Sausure used the classical Greek term for sign, *semeion*, to coin a nomenclature for a new analytical discipline. The two different terminologies are explained, further, by the fact that Peirce and Saussure had no knowledge of each other's work. Moreover, in Saussure's own work, the program for a comprehensive semiology remained undeveloped, appearing almost as an aside compared to his main enterprise of linguistics. It was during the consolidation of semiotics as an interdisciplinary field from the 1960s that this became the agreed term, overriding Peirce's semeiotic and Saussure's semiology, as symbolized by the formation in 1969 of the International Association for Semiotic Studies. It was also during this period that Saussure's systemic approach to language was redeveloped to apply to the study of culture and society.

One important legacy of Saussure has been his account of the arbitrariness of the linguistic sign. This type of sign is said to have two sides, a 'signified' (concept) and a 'signifier' (the acoustic image associated with it), whose relationship is arbitrary or conventional, as suggested by the wealth of terms in different languages for the same phenomenon. This argument has sometimes been construed in relativist terms, as if sign users were paradoxically free to choose their own meanings and, hence, almost destined to remain divorced from each other and any consensual reality. Or, they might be in a position, individually or as subcultures, to reject prevailing conceptions of social reality. The point is, rather, that the linguistic system as a whole is arbitrary, but fixed by social convention. When applied to studies of cultural forms other than language, specifically images, or when extended to the description of social structures as semiotic systems, the principle of arbitrariness has posed certain analytical difficulties, as illustrated in contemporary studies of media, communication, and culture.

Applications: Media, Communication, and Culture

It was the application of semiotics to questions of meaning beyond logic and linguistics that served to consolidate semiotics as a recognizable, if still heterogeneous field from the 1960s onwards. Drawing on additional traditions of aesthetic and social inquiry – from rhetoric and hermeneutics to critical theory – this emerging field began to operationalize the study of 'the life of signs within society.' The objects of analysis ranged widely, from classical artworks to popular culture, and from premodern societies to modern mass media. At the same time, studies were united by a common emphasis on culture, in the broad sense of worldviews that orient social interaction. The work of Claude Lévi-Strauss (1963/1958) on structural anthropology was characteristic of, and highly influential on, this perspective. Structuralism in studies of culture and communication suggested that certain shared, but largely preconscious systems of interpretation help to explain both the ways in which individuals orient themselves and act in specific contexts, and the cultural horizons of an entire society or epoch. It was Saussure's approach to signs as an abstract system (*langue*) which manifests itself in concrete uses (*parole*) that provided the model for structuralism in several fields. The general model was extended, for example, to theories about social power (Althusser, 1977/1965) and about the unconscious understood as a language (Lacan, 1977).

Of the predominantly French scholars who were instrumental in the consolidation of semiotic forms of analysis, Roland Barthes, along with A.J. Greimas, stands out as a particularly innovative and systematic theorist. His specific model of two levels of signification, outlined in **Figure 2**, has been one of the most widely applied approaches to the relationship between concrete sign vehicles, such as texts and images, and the ideologies or myths that they articulate and may reinforce. Building on Louis Hjelmslev's (1963/1943) formal linguistics, Barthes (1973/1957) suggested that the combination of signifier and signified (expressive form and conceptual content) in one sign (e.g., a picture of a black man in a French uniform saluting the flag) may, in a next step, become the expressive form of a further, ideological content (e.g., that French imperialism is not a discriminatory or oppressive system). Barthes' critical agenda, shared by much

Figure 2 Two levels of signification. Adapted from Barthes, R., 1973. Mythologies. Paladin, London. (Original work published 1957.)

semiotic scholarship since then, was that this discursive mechanism serves to naturalize particular worldviews, while oppressing others, and should be exposed through analytical deconstruction.

In a current perspective, social sciences can be seen to have appropriated and redeveloped semiotics in two different ways. On the one hand, semiotics offers rigorous, yet nuanced methodologies for examining how signs enter into social interactions at the individual, group, and institutional levels. Overlapping, in part, with discourse analysis, such methodologies represent the predominant application of the tradition outside philosophy and the subspecialty of semiotics. On the other hand, some scholars have adopted semiotics as a comprehensive theoretical framework, suggesting that not just texts and images, but also societies and psyches, even biology and cosmology, may be conceptualized as semiotic processes (Posner et al., 1997–98).

This last position points to an abiding dilemma for semiotics, namely, its scope and domain of relevance. A conception of semiotics as a theory-of-everything holds several pitfalls, and has given rise to reservations and criticisms. For one thing, such an extension and overlay of logical and linguistic concepts onto other fields and disciplines may conflate different levels of analysis. For another thing, semiotic studies have sometimes focused on the formal aspects of signs and semiotic processes to such an extent that the substantive aspects of the social or cultural domains in question have been neglected. A case in point is research on visual communication, which, in some instances, has referred to Saussure's principle of arbitrariness, deriving from verbal language, to account for both still and moving images. Early work by Christian Metz (1974) did specify that the medium of film does not constitute a language system, analogous to verbal language, but a language or form of communication drawing on several semiotic registers. Later work has reemphasized that audiovisual media, to a significant extent, operate on different perceptual and cognitive modalities than speech and writing, communicating through natural rather than conventional signs (Messaris, 1994).

A related reservation arises from the ambition of much semiotic research to arrive at conclusions regarding the difference that signs make in social practice. Given the predominant focus of semiotic studies on texts and other cultural artifacts, inferences from texts to readings to effects on individuals, groups, or institutions may not be warranted. The textual focus may also exaggerate the extent to which signs in themselves, rather than the social conditions circumscribing them, determine the life of both signs and societies. In recent decades, these concerns have led to efforts at formulating a social semiotics, or sociosemiotics (for overview, see Cobley and Randviir, 2009), integrating semiotic methodology with social theory and communication studies (Hodge and Kress, 1988; Jensen, 1995).

Theory of Signs and Theory of Science

The ambiguous scope of semiotics helps to explain both its continuing influence since Antiquity and the fact that, mostly, it has remained an undercurrent in the theory of science. The understanding, articulated in Aristotle's writings, that signs constitute evidence for an interpreter of something else that is at least temporarily absent – being interfaces with underlying phenomena and processes – can be taken as a civilizational leap that has enabled scientific reflexivity as well as social organization beyond the here and now. The concept of signs, further, has informed the crucial distinction, again deriving from Aristotle, between necessary and probable relations in logical inferences. Returning to the examples above, fever is a sure sign that the person is ill, since illness is a necessary condition of fever. But clouds are only a probable sign of rain. Empirical social sciences have been built on the premise that probable signs can lead to warranted inferences about social events and processes.

The relationship between a theory of signs and a theory of science has been explored primarily from a Peircean perspective. Peirce himself made important contributions to logic and to the theory of science generally, notably by developing 'abduction' as a third form of inference alongside deduction and induction. Abduction introduces a new rule to account for what may appear as surprising facts, and is central to both scientific innovation and everyday reasoning. Moreover, the wider philosophical tradition of pragmatism, which Peirce inaugurated, has emphasized the interrelation between knowledge and action, conceiving belief as an orientation toward action (Joas, 1993). By contrast, the Saussurean tradition has typically bracketed issues concerning "relations between the word and the world" (Jakobson, 1960: 19).

In future research, semiotics is likely to remain a source of inspiration in diverse scientific domains, as it has been for 2500 years. In view of the record from the past century, the field seems less likely to develop into the sort of full-fledged discipline that at least some of its practitioners have sought to promote. One opportunity for semiotics is to consolidate an interdisciplinary framework for exploring how different disciplines and fields conceive of their data and their concepts as signs. The semiotic heritage offers systematic analytical procedures and means of reflexivity regarding the role of signs in society as well as in the social sciences. Another opportunity is for semiotics to refocus attention on a distinctive type of signs that are currently changing social infrastructures around the world: digital signs.

Meta-Signs and Meta-Communication

The digital computer is a semiotic machine *par excellence*. In addition to being one more medium of representation and interaction, computers are able to integrate and simulate all previous media forms. As such, they are meta-media (Kay and Goldberg, 1999/1977). Because computers are programmable, they comprise new types of signs, while simultaneously reproducing familiar signs under different technological circumstances. Some implications of computing for semiotics can be laid out with reference to two concepts: meta-signs and meta-communication (see further Jensen, 2010).

The interface between computers and semiotics has been a topic of inquiry for some time (Andersen, 1990). Digital computers produce a special kind of what computer scientists refer to as 'data' – metadata, or data about data. In semiotic terms, these can be understood as meta-signs, or signs about

Figure 3 Language and meta-language. Adapted from Barthes, R., 1973. Mythologies. Paladin, London. (Original work published 1957.)

signs. Examples include the title, editor, authors, publisher, ISBN number, contents, index, and so on, of the present encyclopedia. In the case of computers, meta-signs indicate not only which items of information are available in a given work, but also which ones are accessed, by whom, at what time, in which formats, and, perhaps, in which combinations, sequences, and contexts of use. Importantly, meta-signs are documented in and of the operation of digital systems, such as search engines. While this feature facilitates the process of searching, it also enables surveillance of the searcher.

It should be emphasized that although meta-signs are key to digital communication systems, they also enter into other forms of communication, including face-to-face interaction. Gregory Bateson (1972) developed the argument that all communication depends on two additional forms of meta-communication. First, we introduce meta-linguistic information into our interactions to specify, for instance, that we mean a reference to clouds to serve as an illustration of a type of sign. Second, we meta-communicate about our relationships as communicators, clarifying whether we are having an academic discussion about semiotics or, alternatively, are referring to clouds as concrete signs that may make us remind each other to bring umbrellas.

A comparable meta-perspective was outlined by Hjelmslev (1943/1963) in parallel with his account of connotation languages, as redeveloped by Barthes (1957/1973) as a tool of semiotic analysis. Connotation languages and meta-languages have different, but complementary relations to their common point of reference, which is first-order language – 'language' as commonly understood and used by humans day in and day out. Connotation languages build on language, and are themselves languages or vehicles of communication, as exemplified by Barthes' myths. They make sense and make a point. Meta-languages, in comparison, describe language: they are not languages in the ordinary sense, but languages about languages, for instance, syntactical or semantic descriptions of the English language.

Figure 3 summarizes the principle of meta-languages. Compared to Barthes' first model (**Figure 2**), this last figure inverses the relation between signifier and signified at the second level of description. Connotation languages add to the meaning or codification of first-level content; meta-languages contribute to configuring the social relationships that people enter into with reference to this content. A linguist, for instance, takes the analyst's rather than the user's stance vis-à-vis language.

Hjelmslev had qualified his account of meta-languages by making an antecedent distinction between scientific and nonscientific languages. Meta-languages were described as scientific languages, defined by their formal operations (but presumably accessible, above all, by expert users of language, such as linguists). In some media and modalities, however, meta-languages can be used by anyone. Ordinary users of digital media, freely and easily, employ a wide variety of such meta-languages, which serve to frame their communicative interactions with others and the contents of those interactions: they tag the blog entries of others; they forward a news story to friends from a website via an embedded email service; they customize their own profiles at social network sites; and they pull a later push of information to themselves through an RSS (Really Simple Syndication) feed. In each case, users add a layer of information that is not part of the content proper, but which facilitates a whole range of communicative interactions.

This relevance of meta-languages, evidently, was not anticipated by Hjelmslev, who devised his models before the coming of digital computing. Also Barthes' appropriation of Hjelmslev's connotation languages for the study of contemporary culture represented an unanticipated application of a general insight. Hjelmslev conceived languages as systems – systems of expression and second-order systems that either build on or describe such systems. Barthes' accomplishment was to transfer this approach to the study of communication as a practice in social contexts. Connotation languages can be examined not only in analytical retrospect, but as they are expressed and take effect. Equally, meta-languages can be understood not merely as analytical systems, but as widespread practices of meta-communication. Meta-languages hold analytical potentials far beyond verbal language and linguistics, reminding interdisciplinary research of the rich heritage of semiotics and its continued relevance for the study of the life of signs in changing societies.

Semiparametric Models

Joel L Horowitz, Northwestern University, Evanston, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Much empirical research in the social sciences is concerned with estimating conditional mean functions. The most frequently used estimation methods assume that the conditional mean function is known up to a set of constant parameters that can be estimated from data. Such methods are called 'parametric.' Their use greatly simplifies estimation and inference but is rarely justified by theoretical or other a priori considerations. Estimation and inference based on convenient but incorrect assumptions about the form of the conditional mean function can be highly misleading. Semiparametric methods reduce the strength of the assumptions required for estimation and inference, thereby reducing the opportunities for obtaining misleading results. In addition, semiparametric methods mitigate certain disadvantages of fully nonparametric methods that make no assumptions about the shape of the conditional mean function. This article describes three important semiparametric models for conditional mean functions. They are single index, partially linear, and additive models. These models are compared with parametric and fully nonparametric models. An example based on real data illustrates the pitfalls of parametric models and the advantages of semiparametric models.

Much empirical research in the social sciences is concerned with estimating conditional mean functions. For example, labor economists are interested in estimating the mean wages of employed individuals, conditional on characteristics such as years of work experience and education. The most frequently used estimation methods assume that the conditional mean function is known up to a set of constant parameters that can be estimated from data, possibly by ordinary least squares (OLS). Models in which the only unknown quantities are a finite set of constant parameters are called 'parametric.' The use of a parametric model greatly simplifies estimation, statistical inference, and interpretation of the estimation results, but is rarely justified by theoretical or other a priori considerations. Estimation and inference based on convenient but incorrect assumptions about the form of the conditional mean function can be highly misleading. Semiparametric statistical methods reduce the strength of the assumptions required for estimation and inference, thereby reducing the opportunities for obtaining misleading results. These methods are applicable to a wide variety of estimation problems in economics and other fields.

Introduction

A conditional mean function gives the mean of a dependent variable Y conditional on a vector of explanatory variables X. Denote the mean of Y conditional on $X = x$ by $E(Y|x)$. For example, suppose that Y is a worker's weekly wage (or, more often in applied econometrics, the logarithm of the wage) and X includes such variables as years of work experience and education, race, and sex. Then $E(Y|x)$ is the mean wage (or logarithm of the wage) when experience and the other explanatory variables have the values specified by x. As an illustration, the solid line in **Figure 1** shows an estimate of the mean of the logarithm of weekly wages, log W, conditional on years of work experience, EXP, for white males with 12 years of education who work full time and live in urban areas of the North Central USA. The estimate was obtained by applying a nonparametric method (explained in Section Nonparametric Models) to data from the 1993 Current Population Survey (CPS). The estimated conditional mean of log W increases steadily up to approximately 30 years of experience and is flat thereafter.

In most applications, $E(Y|x)$ is unknown and must be estimated from data on the variables of interest. In the case of estimating a wage function, the data consist of observations of individuals' wages, years of experience, and other characteristics. The most widely used method for estimating $E(Y|x)$ is not the nonparametric method mentioned previously, but rather a method that assumes that $E(Y|x)$ is known up to finitely many constant parameters. This gives a 'parametric model' for $E(Y|x)$. Often, $E(Y|x)$ is assumed to be a linear function of x, in which case the parameters can be estimated by OLS, among other ways. A linear function has the form $E(Y|x) = \beta' x$, where β is a vector of coefficients. For example, if x consists of an intercept and the two variables x_1 and x_2, then β has three components, and $\beta' x = \beta_0 + \beta_1 x_1 + \beta_2 x_2$. OLS estimators are described in many textbooks. See, for example, Goldberger (1998).

Figure 1 Estimates of $E(\log W|\text{EXP})$.

The OLS estimator of $E(Y|x)$ can be highly misleading if $E(Y|x)$ is not linear in the components of x, that is, if there is no β such that $E(Y|x) = \beta' x$. This problem is illustrated by the dashed and dotted lines in **Figure 1**, which show two parametric estimates of the mean of the logarithm of weekly wages conditional on years of work experience. The dashed line is the OLS estimate, that is, obtained by assuming that $E(\log W|\text{EXP})$ is the linear function $E(\log W|\text{EXP}) = \beta_0 + \beta_1\text{EXP}$. The dotted line is the OLS estimate that is obtained by assuming that $E(\log W|\text{EXP})$ is quadratic: $E(\log W|\text{EXP}) = \beta_0 + \beta_1\text{EXP} + \beta_2\text{EXP}^2$. The nonparametric estimate (solid line) places no restrictions on the shape of $E(\log W|\text{EXP})$. The linear and quadratic models give misleading estimates of $E(\log W|\text{EXP})$. The linear model indicates that $E(\log W|\text{EXP})$ steadily increases as experience increases. The quadratic model indicates that $E(\log W|\text{EXP})$ decreases after 32 years of experience. In contrast, the nonparametric estimate of $E(\log W|\text{EXP})$ becomes nearly flat at approximately 30 years of experience. Because the nonparametric estimate does not restrict the conditional mean function to be linear or quadratic, it is more likely to represent the true conditional mean function.

The opportunities for specification error increase if Y is binary. For example, consider a model of the choice of travel mode for the trip to work. Suppose that the available modes are automobile and transit. Let $Y = 1$ if an individual chooses automobile and $Y = 0$ if the individual chooses transit. Let X be a vector of explanatory variables such as the travel times and costs by automobile and transit. Then $E(Y|x)$ is the probability that $Y = 1$ (the probability that the individual chooses automobile) conditional on $X = x$. This probability will be denoted $P(Y = 1|x)$. In applications of binary response models, it is often assumed that $P(Y|x) = G(\beta' x)$, where β is a vector of constant coefficients and G is a known probability distribution function. Often, G is assumed to be the cumulative standard normal distribution function, which yields a 'binary probit' model, or the cumulative logistic distribution function, which yields a 'binary logit' model. The coefficients β can then be estimated by the method of maximum likelihood (Amemiya, 1985: pp. 115–127). However, there are now two potential sources of specification error. First, the dependence of Y on x may not be through the linear *index* $\beta' x$. Second, even if the index $\beta' x$ is correct, the 'response function' G may not be the normal or logistic distribution function. See Horowitz (1993, 1998) for examples of specification errors in binary response models and their consequences.

Many investigators attempt to minimize the risk of specification error by carrying out a 'specification search' in which several different models are estimated and conclusions are based on the one that appears to fit the data best. Specification searches may be unavoidable in some applications, but they have many undesirable properties and their use should be minimized. There is no guarantee that a specification search will include the correct model or a good approximation to it. If the search includes the correct model, there is no guarantee that it will be selected by the investigator's model selection criteria. Moreover, the search process invalidates the statistical theory on which inference is based. This is because inference following a specification search must be conditional on the selected model, whereas the standard statistical theory of inference is unconditional.

The rest of this article describes methods that deal with the problem of specification error by relaxing the assumptions about functional form that are made by parametric models. The possibility of specification error can be essentially eliminated through the use of nonparametric estimation methods. These are described in Section Nonparametric Models. They assume that $E(Y|x)$ is a smooth function but make no other assumptions about its shape or functional form. However, nonparametric methods have important disadvantages that seriously limit their usefulness in applications. Semiparametric methods, which are described in Section Semiparametric Models offer a compromise. They make assumptions about functional form that are stronger than those of a nonparametric model but less restrictive than the assumptions of a parametric model, thereby reducing (though not eliminating) the possibility of specification error. In addition semiparametric methods avoid the most serious practical disadvantages of nonparametric methods.

Nonparametric Models

In nonparametric estimation, $E(Y|x)$ is assumed to satisfy smoothness conditions such as differentiability, but no assumptions are made about its shape or the form of its dependence on x. Härdle (1990) and Fan and Gijbels (1996) provide detailed discussions of nonparametric estimation methods. One easily understood and frequently used method is called 'kernel estimation.' This method was used to produce the solid line in **Figure 1**. To describe the kernel method simply, assume that X is a continuously distributed, scalar random variable. Let $\{Y_i, X_i: i = 1, \ldots, n\}$ be a random sample of n observations of (Y, X). Let K be a probability density function that is bounded, continuous, and symmetrical about zero. For example, K may be the standard normal density function. Let $\{h_n\}$ be a sequence of positive numbers that converges to 0 as $n \to \infty$. For each $n = 1, 2, \ldots$ and $i = 1, \ldots, n$ define the function $w_{ni}(\cdot)$ by

$$w_{ni}(x) = \frac{K[(x - X_i)/h_n]}{\sum_{i=1}^{n} K[(x - X_i)/h_n]} \qquad [1]$$

Then the kernel nonparametric estimator of $E(Y|x)$ is

$$H_n(x) = \sum_{i=1}^{n} w_{ni}(x) Y_i \qquad [2]$$

$H_n(x)$ is a weighted average of the observed values of Y. Observations Y_i for which X_i is close to x get higher weight than do observations for which X_i is far from x. It can be shown that if $h_n \to 0$ and $nh_n/\log n \to \infty$ as $n \to \infty$, then $H_n(x) \to E(Y|x)$ with probability 1. Thus, if n is large, $H_n(x)$ is likely to be very close to $E(Y|x)$. Härdle (1990) provides a detailed discussion of the statistical properties of kernel nonparametric estimators.

Nonparametric estimation minimizes the risk of specification error, but the price of this flexibility can be high. One important reason for this is that the precision of a nonparametric estimator decreases rapidly as the number of continuously distributed components of X increases. This phenomenon is called the 'curse of dimensionality.' As a result

of it, impracticably large samples are usually needed to obtain acceptable estimation precision if X is multidimensional, as it often is in social science applications. For example, a labor economist may want to estimate mean log wages conditional on years of work experience, years of education, and one or more indicators of skill levels, thus making the dimension of X at least 3. (*See* Nonparametric Regression for further discussion of the curse of dimensionality.)

Another problem is that nonparametric estimates can be difficult to display, communicate, and interpret when X is multidimensional. Nonparametric estimates do not have simple analytic forms, so displaying and interpreting them can be difficult. If X is one- or two-dimensional, then the estimate of $E(Y|x)$ can be displayed graphically as in **Figure 1**, but only reduced-dimension projections can be displayed when X has three or more components. Many such displays and much skill in interpreting them can be needed to fully convey and comprehend the shape of the estimate of $E(Y|x)$.

Another problem with nonparametric estimation is that it does not permit extrapolation. That is, it does not provide predictions of $E(Y|x)$ at points x that are outside of the support (or range) of the random variable X. This is a serious drawback in policy analysis and forecasting, where it is often important to predict what might happen under conditions that do not exist in the available data. Finally, in nonparametric estimation, it can be difficult to impose restrictions suggested by economic or other theory. Matzkin (1994) discusses this issue.

Semiparametric methods permit greater estimation precision than do nonparametric methods when X is multidimensional. In addition, semiparametric estimates are easier to display and interpret than nonparametric ones and provide limited capabilities for extrapolation and imposing restrictions derived from economic or other theory models.

Semiparametric Models

The term 'semiparametric' refers to models in which there is an unknown function in addition to an unknown finite dimensional parameter. For example, the binary response model $P(Y=1|x)=G(\beta'x)$ is semiparametric if the function G and the vector of coefficients β are both treated as unknown quantities. This section describes two semiparametric models of conditional mean functions that are important in applications. The section also describes a related class of models that have no unknown finite-dimensional parameters but, like semiparametric models, mitigate the disadvantages of fully nonparametric models.

In addition to the estimation of conditional mean functions, semiparametric methods can be used to estimate conditional quantile and hazard functions, binary response models in which there is heteroskedasticity of unknown form, transformation models, and censored and truncated mean- and median- regression models, among others. Space does not permit discussion of these models here. Horowitz (1998, 2009), Li and Racine (2007), and Powell (1994) provide more comprehensive treatments in which these models are discussed.

Single-Index Models

In a semiparametric single-index model, the conditional mean function has the form

$$E(Y|x) = G(\beta'x) \qquad [3]$$

where β is an unknown constant vector and G is an unknown function. The quantity $\beta'x$ is called an 'index.' The inferential problem is to estimate G and β from observations of (Y, X). G in eqn [3] is analogous to a link function in a generalized linear model, except in eqn [3] G is unknown and must be estimated.

Equation [3] contains many widely used parametric models as special cases. For example, if G is the identity function, then eqn [3] is a linear model. If G is the cumulative normal or logistic distribution function, then eqn [3] is a binary probit or logit model. When G is unknown, eqn [3] provides a specification that is more flexible than a parametric model but retains many of the desirable features of parametric models, as will now be explained.

One important property of single-index models is that they avoid the curse of dimensionality. This is because the index $\beta'x$ aggregates the dimensions of x, thereby achieving 'dimension reduction.' Consequently, the difference between the estimator of G and the true function can be made to converge to zero at the same rate that would be achieved if $\beta'x$ were observable. Moreover, β can be estimated with the same $n^{-1/2}$ rate of convergence that is achieved in a parametric model. Thus, in terms of the rates of convergence of estimators, a single-index model is as accurate as a parametric model for estimating β and as accurate as a one-dimensional nonparametric model for estimating G. This dimension reduction feature of single-index models gives them a considerable advantage over nonparametric methods in applications where X is multidimensional and the single-index structure is plausible.

A single-index model permits limited extrapolation. Specifically, it yields predictions of $E(Y|x)$ at values of x that are not in the support of X but are in the support of $\beta'X$. Of course, there is a price that must be paid for the ability to extrapolate. A single-index model makes assumptions that are stronger than those of a nonparametric model. These assumptions are testable on the support of X but not outside of it. Thus, extrapolation (unavoidably) relies on untestable assumptions about the behavior of $E(Y|x)$ beyond the support of X.

Before β and G can be estimated, restrictions must be imposed that ensure their identification. That is, β and G must be uniquely determined by the population distribution of (Y, X). Identification of single-index models has been investigated by Ichimura (1993) and, for the special case of binary response models, Manski (1988). It is clear that β is not identified if G is a constant function or there is an exact linear relation among the components of X (perfect multicollinearity). In addition, eqn [3] is observationally equivalent to the model $E(Y|x)=G^*(\gamma+\delta\beta'x)$, where γ and $\delta \neq 0$ are arbitrary and G^* is defined by the relation $G^*(\gamma+\gamma v)=G(v)$ for all v in the support of $\beta'X$. Therefore, β and G are not identified unless restrictions are imposed that uniquely specify γ and δ. The restriction on γ is called 'location normalization' and can be imposed by requiring X to contain

no constant (intercept) component. The restriction on δ is called 'scale normalization.' Scale normalization can be achieved by setting the β coefficient of one component of X equal to one. A further identification requirement is that X must include at least one continuously distributed component whose β coefficient is nonzero. Horowitz (1998, 2009) gives an example that illustrates the need for this requirement. Other more technical identification requirements are discussed by Ichimura (1993) and Manski (1988).

The main estimation challenge in single-index models is estimating β. Given an estimator b_n of β, G can be estimated by carrying out the nonparametric regression of Y on $b_n'X$ (e.g., by using the kernel method described in Section Nonparametric Models). Several estimators of β are available. Ichimura (1993) describes a nonlinear least squares estimator. Klein and Spady (1993) describe a semiparametric maximum likelihood estimator for the case in which Y is binary. These estimators are difficult to compute because they require solving complicated nonlinear optimization problems. Xia et al. (2002) and Xia (2006) discuss computation of the estimator of Ichimura (1993).

Powell et al. (1989) describe a 'density-weighted average derivative estimator' (DWADE) that is non-iterative and easily computed. The DWADE applies when all components of X are continuous random variables. It is based on the relation

$$\beta E[p(X)\partial G(\beta' X)/\partial X] = -2E[Y\partial p(X)/\partial X] \qquad [4]$$

where p is the probability density function of X and the second equality follows from integrating the first by parts. Thus, β can be estimated up to scale by estimating the expression on the right-hand side of the second equality. Powell et al. (1989) show that this can be done by replacing p with a nonparametric estimator and replacing the population expectation E with a sample average.

To achieve an $n^{-1/2}$ rate of convergence of b_n to β, the DWADE of Powell et al. (1989) requires p to have more derivatives when the dimension of X is large than when it is small. A practical consequence of this property is that the accuracy of the DWADE tends to decrease as the dimension of X increases. This problem can be overcome by using an average derivative estimator proposed by Hristache et al. (2001a). See, also, Cattaneo et al. (2014).

Ichimura and Lee (1991) and Hristache et al. (2001b) investigate a multiple index generalization of eqn [3]. Horowitz and Härdle (1996) extend the DWADE to models in which some components of X are discrete. They also give an empirical example that illustrates the usefulness of single-index models. Ichimura and Lee (1991) investigate a multiple index generalization of eqn [3].

Partially Linear Models

In a partially linear model, X is partitioned into two nonoverlapping subvectors, X_1 and X_2. The model has the form

$$E(Y|x_1, x_2) = \beta' x_1 + G(x_2) \qquad [5]$$

where β is an unknown constant vector and G is an unknown function. This model is distinct from the class of single-index models. A single-index model is not partially linear unless G is a linear function. Conversely, a partially linear model is a single-index model only in this case. Stock (1989, 1991) and Engle et al. (1986) illustrate the use of eqn [5] in applications. Identification of β requires the 'exclusion restriction' that none of the components of X_1 are perfectly predictable by components of X_2. When β is identified, it can be estimated with an $n^{-1/2}$ rate of convergence regardless of the dimensions of X_1 and X_2. Thus, the curse of dimensionality is avoided in estimating β.

An estimator of β can be obtained by observing that eqn [5] implies

$$Y - E(Y|x_2) = \beta'[X_1 - E(X_1|x_2)] + U \qquad [6]$$

where U is an unobserved random variable satisfying $E(U|x_1,x_2) = 0$. Robinson (1988) shows that under regularity conditions β can be estimated by applying OLS to eqn [6] after replacing $E(Y|x_2)$ and $E(X_1|x_2)$ with nonparametric estimators. The estimator of β, b_n, converges at rate $n^{-1/2}$ and is asymptotically normally distributed. G can be estimated by carrying out the nonparametric regression of $Y - b_n'X_1$ on X_2. Unlike b_n, the estimator of G suffers from the curse of dimensionality; its rate of convergence decreases as the dimension of X_2 increases.

Härdle et al. (2000) provide a more detailed discussion of partially linear models. Xia and Härdle (2006) consider a version of eqn [5] in which $G(X_2)$ is replaced with the single-index form $G(\gamma' X_2)$, where γ is a constant vector.

Nonparametric Additive Models

Let X have d continuously distributed components that are denoted $X_1, \ldots, X_d$. In a nonparametric additive model of the conditional mean function,

$$E(Y|x) = \mu + f_1(x_1) + \cdots + f_d(x_d) \qquad [7]$$

where μ is a constant and $f_1, \ldots, f_d$ are unknown functions that satisfy a location normalization condition such as

$$\int f_k(v) w_k(v) \mathrm{d}v = 0, \quad k = 1, \ldots, d \qquad [8]$$

where w_k is a nonnegative weight function. An additive model is distinct from a single-index model unless $E(Y|x)$ is a linear function of x. Additive and partially linear models are distinct unless $E(Y|x)$ is partially linear and G in eqn [5] is additive.

An estimator of $f_k (k = 1, \ldots, d)$ can be obtained by observing that eqns [7] and [8] imply

$$f_k(x_k) = \int E(Y|x) w_{-k}(x_{-k}) \, dx_{-k} \qquad [9]$$

where x_{-k} is the vector consisting of all components of x except the kth and w_{-k} is a weight function that satisfies $\int w_{-k}(x_{-k}) \mathrm{d}x_{-k} = 1$. The estimator of f_k is obtained by replacing $E(Y|x)$ on the right-hand side of eqn [9] with nonparametric estimators. Linton and Nielsen (1995) and Linton (1997) present the details of the procedure, which is called 'marginal integration,' and extensions of it. Under suitable conditions, the estimator of f_k converges to the true f_k at rate $n^{-2/5}$ regardless of the dimension of X. Thus, the additive model provides dimension reduction. It also permits extrapolation of $E(Y|x)$ within the

rectangle formed by the supports of the individual components of X. Hastie and Tibshirani (1990) discuss an alternative estimation procedure called 'backfitting.' This procedure is widely used, but its asymptotic properties are not yet well understood.

Linton and Härdle (1996) describe a generalized additive model whose form is

$$E(Y|x) = G[\mu + f_1(x_1) + \cdots + f_k(x_d)] \qquad [10]$$

where $f_1, \ldots, f_d$ are unknown functions and G is a known, strictly increasing (or decreasing) function. Horowitz (2001) and Horowitz and Mammen (2007, 2011) present estimators of a version of eqn [10] in which G is unknown. Both forms of eqn [10] achieve dimension reduction. When G is unknown, eqn [10] nests additive and single-index models and, under certain conditions, partially linear models.

To achieve an $n^{-2/5}$ rate of convergence of the estimators of the f_k's, the marginal integration method requires the f_k's to have more derivatives when the dimension of X is large than when it is small. As with the DWADE, a practical consequence of this property is that the accuracy of the marginal integration estimator tends to decrease as the dimension of X increases. Mammen et al. (1999), Horowitz and Mammen (2004), and Yu et al. (2008) present estimators that overcome this problem. Wang and Yang (2007) and Song and Yang (2010) present estimation methods for time series data.

Figure 2 (a) Estimate of f_{EXP} in additive nonparametric model of $E(\log W|\text{EXP,EDUC})$. (b) Estimate of f_{EDUC} in additive nonparametric model of $E(\log W|\text{EXP,EDUC})$.

The use of the nonparametric additive specification (eqn [7]) can be illustrated by estimating the model

$$E(\log W|\text{EXP}, \text{EDUC}) = \mu + f_{\text{EXP}}(\text{EXP}) + f_{\text{EDUC}}(\text{EDUC})$$

where W and EXP are defined as in Section Introduction, and EDUC denotes years of education. The data are taken from the 1993 Current Population Survey and are for white males with 14 or fewer years of education who work full time and live in urban areas of the North Central US. The results are shown in **Figure 2**. The unknown functions f_{EXP} and f_{EDUC} are estimated by the method of Linton and Nielsen (1995) and are normalized so that $f_{\text{EXP}}(2) = f_{\text{EDUC}}(5) = 0$. The estimates of f_{EXP} (**Figure 2(a)**) and f_{EDUC} (**Figure 2(b)**) are nonlinear and differently shaped. Functions f_{EXP} and f_{EDUC} with different shapes cannot be produced by a single-index model, and a lengthy specification search might be needed to find a parametric model that produces the shapes shown in **Figure 2**. Some of the fluctuations of the estimates of f_{EXP} and f_{EDUC} may be artifacts of random sampling error rather than features of $E(\log W|\text{EXP,EDUC})$. However, a more elaborate analysis that takes account of the effects of random sampling error rejects the hypothesis that either function is linear.

Conclusions

This article has described several semiparametric methods for estimating conditional mean functions. These methods relax the restrictive assumptions made by linear and other parametric models, thereby reducing (though not eliminating) the likelihood of seriously misleading inference. The value of semiparametric methods in empirical research has been demonstrated. Their use is likely to increase as their availability in commercial statistical software packages increases.

Sensation and Perception: Direct Scaling

Martha Teghtsoonian, Smith College, Northampton, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Two techniques for the direct scaling of perceived intensity – category and magnitude judgments – are described. The major findings associated with direct scaling are the establishment of Stevens's power law of perceived intensity, the establishment of characteristic exponents for the several sensory continua, and the discovery of the transitivity of exponents. Major problems of direct scaling, and of the body of work based on it, include the failure of category and magnitude scales to agree, the instability of exponents, and the difficulty of integrating results of scaling suprathreshold magnitudes with data on sensory thresholds. Possible resolutions of these difficulties are presented.

One aim of psychophysics is to measure the perceived intensity of any given stimulus level. We easily hear that a tone at a given sound pressure level has a particular loudness and that a tone at a higher level sounds louder still. The measurement problem lies in the question 'How much louder?' Direct scaling is a particular way of answering that question: the observer is asked to assign numbers corresponding to the perceived intensities, the subjective magnitudes, of given stimulus intensities.

History

Fechner's Solution

G. Fechner proposed a solution to the question of 'How loud?', albeit an indirect one, in 1860 (Boring, 1950). He accepted Weber's law – that the difference threshold (the physical size of a difference in intensity needed to tell one signal from another) grows in proportion to signal intensity, determining a constant of proportionality, the Weber fraction, unique to each sensory continuum. Fechner assumed that all difference thresholds on a given sensory continuum are subjectively equal and therefore can serve as the unit of measurement for scales of sensation. He concluded that subjective magnitude grows by constant differences as stimulus magnitude grows by constant ratios, a logarithmic relation now known as Fechner's law.

Category Rating and Magnitude Scaling

In Fechner's laboratory, there also evolved a direct approach to measuring subjective magnitude. This was the method of absolute judgment (later called category rating), in which the subject assigns stimuli to categories according to some subjective aspect. Originally designed to study esthetic judgment, it was adapted by 1920 to study perceived intensity; early findings using this method supported Fechner's law.

In the 1950s, S. S. Stevens proposed another version of direct scaling in which the subject estimates the apparent magnitude of a signal by assigning to it a numerical value – hence, magnitude estimation.

Methods

The direct scaling methods require an observer to judge a series of stimuli varying along (at least) one dimension. For instance, the experimenter might present a pure tone at several sound pressure levels covering a 1000:1 range and request judgments of loudness, or present a disk of light at several luminances covering a 10:1 range and request judgments of brightness.

Category Rating

The observer is instructed to assign each stimulus to a category, which may be designated descriptively (very soft, soft,…, very loud) or numerically (1, 2,…, 7); the assignments should create subjectively equal intervals. The allowable response values, including the extreme values, are specified by the experimenter. Usually, the number of categories ranges from 5 to 11, although smaller and larger values are sometimes used. Typically, the stimulus range does not exceed 10:1, although it may do so.

Magnitude Estimation and Production

In magnitude estimation, the observer is instructed to assign to each stimulus a (positive) number that reflects its apparent magnitude. There are no limits on allowable response values. Originally, one stimulus value was designated as standard and a numerical value assigned to it as modulus. Later, however, the use of designated standard and assigned modulus was abandoned, and the observer was instructed to choose any numerals appropriate to represent apparent magnitudes. The stimulus range may be 100:1 and is often greater.

In magnitude production, stimulus and judgmental continua are interchanged: the experimenter presents a set of numbers, and the observer produces values on some intensive continuum to effect a subjective match for each presented number.

Cross-Modal Matching

The use of numbers, which provoked many objections, can be avoided by instructing the observer to match intensities on one physical continuum directly to intensities on another (Stevens and Mack, 1959). For example, the observer may adjust luminances to match sound pressure levels so that the brightness of a disk of light seems equivalent to the loudness

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43087-4

of a tone, or the observer may produce handgrip forces to match odor intensities so that the perceived effort is equivalent to the strength of smell.

Achievements of Direct Scaling

A Quantitative Phenomenology

These methods made possible a quantitative phenomenology of the various sensory systems. For example, in hearing, the relevance of variables such as frequency and intensity to the ability of the observer to detect a sound or to tell the difference between two sounds had long been known. Furthermore, by having the observer match tones of varying frequency and intensity to a fixed reference tone, equal loudness contours were established. What remained unknown were the loudness relations among these contours. If it can be assumed that the numerals used by observers correspond directly to the number scale, then magnitude estimation provides a reference scale: we can say that one tone sounds twice, or 10 times, or half as loud as another. Magnitude estimation has been used to map the effects of variables known to influence perception for loudness, brightness, tastes and smells, and tactile sensations, as well as internal states such as perceived effort, fatigue, and satiety (Stevens, 1975). It has also been used to study continua without a physical measure (e.g., seriousness of crime, severity of punishment, and their relationship) (Sellin and Wolfgang, 1964).

Category rating has been employed to study the cognitive integration of perceptual dimensions (Anderson, 1981). A version of the category scale, the Borg scale (Borg, 1998) has seen wide use in practical settings.

Intermodal Comparisons

Direct scaling also provides the capability to compare and contrast phenomena that occur in several modalities, such as temporal and spatial summation, sensory adaptation and recovery, and spatial inhibition (brightness contrast and auditory masking), at levels above absolute threshold (Marks, 1974). For example, the smell associated with a persisting olfactory stimulus of constant intensity diminishes in strength over time (adaptation). That diminution can be assessed by asking an observer to assign numbers to the apparent magnitude of the smell at different elapsed times, e.g., after 5, 10, 30, 60 s,…; in this way, the course of sensory adaptation can be traced for this stimulus and for others of differing initial intensities. When the procedure is repeated in a different modality, the parameters of the adaptation curves can be compared.

Stevens's Power Law

The third major achievement of direct scaling is the discovery that, to at least a first approximation, equal stimulus ratios produce equal judgmental ratios. This nearly universal relation is called Stevens's power law, after S. S. Stevens who established it: subjective magnitude is proportional to stimulus intensity raised to some power. Further, that exponent takes distinctive values for each stimulus continuum, ranging from 0.3 for luminance to 2.0 or more for electric shock. When the exponent is less than 1.0, the sensory system in question is compressive – a wide physical range becomes a much smaller perceptual range. When the exponent is greater than 1.0, the sensory system is expansive – a small physical range becomes a much larger perceptual range.

Furthermore, these magnitude exponents predict cross-modal matching exponents: if continua A and B have magnitude exponents a and b, and if a cross-modal match of B to A is obtained, the resulting exponent is a/b. Indeed, the cross-modal exponents for a variety of continua are connected in a transitive network at the level of the individual observer (Daning, 1983).

Problems of Direct Scaling

The Instability of the Exponent

Critics have characterized the search for exponents characteristic of each sensory continuum as futile, since obtained exponent values are (1) so dependent on contextual factors (e.g., range of stimuli, sequence in which stimuli occur, and numerals chosen by the observer) (Lockhead, 1992) and (2) subject to the so-called regression effect (the value of the exponent relating two continua depends on which serves as the target and which as the matching continuum). A reply to these critics (Teghtsoonian and Teghtsoonian, 2003) argued that there are several answers to these criticisms. First, some of these objections, on closer examination, are not supported by data. Second, experiments can identify the sources of some biases and show ways in which they can be controlled. Third, the understanding of context effects and biases can be extended by models of judgmental data. For example, DeCarlo (2005), in an examination of the regression effect, provided theoretical and empirical support for the conjecture that the geometric mean of the two exponents in a cross-modal matching experiment gives an unbiased estimate of the true exponent.

Category vs. Ratio Scales

Although both category rating and magnitude estimation purport to give scales of sensation magnitude, they do not, in general, agree with each other: both scales can be characterized as power functions, but the exponents are not the same. Much discussion has centered on whether subjects can make two kinds of judgments or whether the experimenter transforms a single kind of magnitude judgment by treating it as a ratio or an interval. However, an experimental determination of the sources of variance in the type of scale produced showed that instructions to judge either ratios or intervals accounted for almost none of the variance; much more important were such methodological variables as whether judgmental end points were assigned or free and whether the range of stimuli was small or large. With free end points and a large range, category judgment and magnitude estimation produce the same results, and the obtained power functions have stable exponents characteristic of magnitude estimation (Montgomery, 1975).

Local vs. Global Psychophysics

A long-standing conundrum in psychophysics has been the relation between the local (thresholds, both absolute and

differential) and the global (measurements of subjective magnitude at levels above the absolute threshold) (Luce and Krumhansl, 1988). Fechner believed he had combined the two by using difference thresholds as subjective units to yield a logarithmic scale of sensation. Stevens (1961) proposed, while honoring Fechner, to repeal his law and to substitute a power scale of sensation; he believed that one could not derive measures of sensation magnitude from threshold determinations. Teghtsoonian (1971, 2012) reconciled these two positions by arguing that both difference thresholds and power law exponents are indices of dynamic range (the range from the smallest stimulus discernible to the greatest stimulus to which the sensory system can respond differentially). He proposed that there is a common scale of sensory magnitude for all perceptual continua and that the observer's dynamic range for each continuum maps completely onto that common scale. For example, the least sound intensity experienced may have the same subjective magnitude as the least luminance, and the greatest sound intensity to which the auditory system responds may have the same subjective magnitude as the greatest luminance. Thus the mapping of widely divergent dynamic ranges for the several perceptual continua onto a single subjective magnitude range will determine their power law exponents, and the mapping of widely divergent difference thresholds onto a single subjective difference threshold will determine their Weber fractions.

Use of Numerals as Responses

Critics have questioned whether the numerals assigned by the observer can be taken to correspond to the number scale. Narens (1996) and Luce (2002) have proposed axiomatizations of direct scaling (magnitude estimation and ratio production, respectively) and have shown that two conditions – commutativity and multiplicativity – must be satisfied by the observers' use of numerals if those numerals can be taken to establish a number scale. Empirical studies have shown in at least two cases that scaling judgments are commutative but not multiplicative (Zimmer, 2005).

These findings do not vitiate the achievements outlined above – the establishment of a quantitative phenomenology, the possibility of cross-continuum comparison of perceptual phenomena, and the ubiquity of Stevens's power law. They leave open the question with which we began: Can the observer's responses tell us how much louder (or brighter or heavier) one stimulus seems than another? We do not yet know how to measure sensation, and it may be that it is not measurable.

Sensation Seeking: Behavioral Expressions and Biosocial Bases

Marvin Zuckerman, University of Delaware, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The development of questionnaire scales to measure sensation seeking, first as a general trait and then as one with two or four facets, is described. Behavioral correlates of the trait include: volunteering for unusual or risky experiences, exceptional dangerous sports, fast and reckless driving, variety of sexual partners and activities, smoking, drinking and drugs, and risky or stressful vocations. Sensation seeking also influences preferences in art, media, music, movies, and television with a preference for novel, intense, and arousing themes like sex and violence.

There is a strong genetic influence in sensation seeking, compared to other personality traits. Biochemical correlates include testosterone, dopamine, and serotonin, and the genes and enzymes that regulate them. Sensation seeking also correlates with cortical reactivity to intensity of stimuli. Parallel studies of other species suggest that sensation seeking has evolved from a strong approach trait, including exploration, and a weak behavioral inhibition mechanism. Similar biological mechanisms underlie the behavioral dispositions in human and nonhuman species.

Definition

Most definitions of personality traits are based on little more than a theoretical concept and the content of the items making up the scale. However the ultimate definition of a construct should go beyond an operational definition tied to a single method of assessment. It should be based upon the body of research relating the construct to external measures derived from the theory of the construct. The construct definition may change and evolve as we test the *construct validity* of our initial and subsequent measures (Cronbach and Meehl, 1955).

Sensation seeking (SS) was initially based on Hebb's (1955) model of an optimal level of cortical arousal (OLA) for learning and performance with the added postulation of individual differences in reticulo-cortical reactivity (Zuckerman, 1969). Subsequent research over the years led to a broader construct with a different biological basis (Zuckerman, 1979, 1994, 2007). The OLA theory was based on the relationship between stimulus intensity and cortical arousal. Newer research on the content of the predictor scales and the predicted phenomena led to the inclusion of stimulus novelty as well as intensity in the qualities of stimuli motivating SS and avoidance. The current behavioral definition of the trait is:

> Sensation seeking is a trait defined by the seeking of varied, novel, complex, and intense sensations and experiences, and the willingness to take physical, social, legal, and financial risks for the sake of such experience.
>
> Zuckerman, 1994: p. 27

Three books (Zuckerman, 1979, 1994, 2007) describe the methods of assessment of the trait and the behavioral and psychobiological research on the trait. The last of these (Zuckerman, 2007) emphasizes the research on risky behavior. Not all behavioral characteristic of high sensation seekers is risky: for instance, their seeking of vicarious experience in movies, art, music, and media with the qualities of stimuli they find pleasurably exciting even if the content is negative (Zuckerman, 2006). The biosocial basis of SS has evolved and changed with new methods and findings. Aside from the three SS books it is described in two other volumes (Zuckerman, 1991, 2005) on the psychobiology of personality in general.

Different names have been given to traits assessed by other measures but quite similar to SS in theory and content. Examples are: change seeking, stimulus variation seeking, excitement seeking, fun seeking, venturesomeness, and novelty seeking (NS). Lack of attention to *convergent and discriminant validation* (Campbell and Fiske, 1959) has led to a needless proliferation of constructs primarily distinguished by their labels rather than their substance. Of course there is always some variation due to specific measures but this method variance is generally not of much interest in personality science. However facets within a major trait may be of theoretical interest and have differential prediction. Such facets have been developed for SS and will be described in the next section.

Development of Sensation Seeking Scales

Form II

Items were written for the first experimental form of the sensation seeking scale (SSS) based on the theory of individual differences in OLA or intensity of stimulation, although some reflecting a need for novelty were also included, as were items endorsing a desire to engage in risky sports or activities (thrill seeking). Factor analyses of items yielded a general sensation seeking (GSS) factor defined by the first unrotated factor. The GSS was the basis of the SSS II (Zuckerman et al., 1964). The forced-choice item response form was used in an attempt to control social desirability which was considered an important determinant of test results at that time.

Forms IV and V

In the development of form II we noticed some indications of additional subfactors but there were not enough items in form I to ascertain their content through rotation of factors. Experimental form III included a wider diversity of items although we

were not certain what content form would describe these factors. Rotation did show four reliable subfactors or facets constituting SSS form IV (Zuckerman, 1971).

1. Thrill and adventure seeking (TAS) items express a desire to seek excitement through unusual or exceptional sports such as skydiving or scuba diving.
2. Experience seeking (ES) items describe a desire to have novel experiences through travel, drugs, and a spontaneous, nonconforming lifestyle with unusual, exciting friends.
3. Disinhibition (Dis) items refer to seeking variety and arousal through social and sexual stimulation, lively parties, and social drinking.
4. Boredom susceptibility (BS) items express an aversion to lack of change and variety of experiences and boring people.

Form IV also included the GSS scale from form II as a measure of the overall factor.

Form V was developed from the items in form IV, selecting the highest loading 10 items from each rotated factor in new samples of American and British subjects (Zuckerman et al., 1978). The factors were reliable and there was little or no loss of internal reliability in the shortened scales. Instead of the GSS, a general factor was assessed as the total of the scores on the four subscales. The four-factor structure of SSS using the original pool of items has been consistently replicated in other countries and languages (Zuckerman, 1994). SSS developed from analyses of the broad personality questionnaires.

Impulsive Sensation Seeking

Factor analyses of scales measuring a broad sample of traits associated with biological factors in personality consistently yielded five major factors: sociability, neuroticism, impulsive sensation seeking (ImpSS), aggression, and activity, comprising the Zuckerman–Kuhlman Personality Questionnaire (ZKPQ; Zuckerman et al., 1993).

The ImpSS scale differed in three important ways from the SSS II to V scales. First, the response format was changed from the forced-choice form to a simpler true–false form. Second, references to specific activities like drinking, drugs, and sex were eliminated and converted to more general statements. The specific items had been confounded in the many studies of actual behavior like drinking, taking drugs, and sexual experience. Third, because of the limited sampling of items specific to the four subscales of the SSS these four factors could not appear. Instead, SSS items were highly related to a type of impulsivity: acting on impulse without planning or anticipation of risk. The Imp and SS components of ImpSS may be scored separately or together. The Total scale has 19 items.

ImpSS from the Cross-Cultural Shortened Form of the ZKPQ (ZKPQ-50-cc)

Aluja et al. (2006) developed a short form of the ZKPQ in four countries, each one using a different language (English, French, German, and Spanish). Reliable and similar factors were found across languages. The 10-item ImpSS scale alpha reliabilities ranged from 0.72 to 0.74 in the four samples. The shortened ImpSS scale contains eight SS items but only two Imp items; therefore these two components should not be scored separately.

The SSS from the Zuckerman–Kuhlman–Aluja Personality Questionnaire

Aluja et al. (2010) developed a new form of the ZKPQ containing four facets for each of the five major factors. Many new items were written for the experimental form but as with the ZKPQ not using items with specific content for drinking, drugs, or sex. The item response format was a 4-point Likert scale. Possible facets for the SS factor included the four factors from the original SSS plus an impulsivity facet, like the one in the ZKPQ and an antisocial SS facet. Factor analyses of items within factors yielded three of the original SSS facets (TAS, ES, and Dis) but the fourth facet was a combination of BS and impulsivity items (BS/Imp). Antisocial SS did not emerge as a fifth facet. Factor analyses of the 20 facets yielded the postulated structure with all four facets loading highest on the appropriate factor and much lower on the other four factors.

Up to now the majority of research on sensation seeking has been done with the SSS-V and its subscales. However since the SSS in the ZKPQ contains substantially the same four subscales without the confounding content of the SSS-V and the sometimes difficult forced-choice response format, it is recommended that future research consider using the 40-item SSS from the Zuckerman–Kuhlman–Aluja Personality Questionnaire (ZKA-PQ).

Behavioral Expressions

Volunteering

The first studies of sensation seeking involved the prediction of reactions to the experimental situation of sensory deprivation (SD) (Zuckerman, 1969). The theory of OLA predicted that persons with high needs for stimulation would be more stressed by a situation where they were deprived of external stimulation. High sensation seekers did become more bored and restless during SD, but an unpredicted finding was that the volunteers for SD were disproportionally drawn from the high SS subjects. Asked why they volunteered, they replied that they expected to have hallucinations and experience unusual mental states. The need for novelty was more important than the need for intensity. In subsequent studies of volunteering, high sensation seekers tended to volunteer for other experiments involving hypnosis, taking hallucinogenic drugs, and encounter groups, but not for more mundane experiments in learning or social psychology.

Within the U.S. Army (Jobe et al., 1983) and Israeli Army and population, volunteers for risky missions or jobs were high sensation seekers. Among soldiers exposed to combat in Israel during the Yom Kippur War, those decorated for bravery in combat were higher than other battle veterans in sensation seeking (Neria et al., 2000). The sensation seeking trait plays a role beyond patriotism, loyalty to comrades, and other motives of heroism. What of physical risky behavior outside of war?

Sports

Replicated studies have shown that those who engage in exceptional and risky sports like mountain climbing, skydiving, scuba diving, whitewater canoeing, and hang gliding are high sensation seekers, but the larger number who engage in ordinary sports like football, baseball, and tennis, and physical education students are only average on this trait. Those who engage in sports requiring dedicated training or endurance like golf and marathon running tend to be low in sensation seeking. The sports that attract high sensation seekers involve novel or unusual and sometimes intense sensations and experiences outside the realm of ordinary life activities. However there is one more common life activity where high sensation seekers find expression despite the physical and legal risks involved.

Driving

Both self-report and observational studies show that high sensation seekers tend to drive recklessly at high speeds, following too closely to cars in front of them, driving while intoxicated, driving with frequent and abrupt lane changes, and generally aggressive driving. From a review of 40 studies, Jonah (1997) concluded that sensation seeking was significantly related to such indices of reckless driving in the great majority of these studies. Observations of drivers (Burns and Wilde, 1995; Heino, 1996) over preselected routes show that high sensation seekers do drive faster and more recklessly than low sensation seekers. Burns and Wilde also showed a correlation with records of past violations.

Sex

Risk-taking in sexual behavior is the source of both extreme pleasure and pain in human relationships. Novelty and variety enhance arousal, and familiarity tends to reduce it. High sensation seekers tend to seek sensation through a variety of sexual partners and activities (Zuckerman et al., 1976). Hoyle et al. (2000) reviewed all studies (up to 1999) relating sexual risk-taking to major personality traits. Sexual risk-taking was defined by number of partners, unprotected sex, and high-risk sexual encounters (like sex with a stranger). Sensation seeking was related to all three categories of risk, and correlations with the SSS were higher than for nearly all other personality traits.

Unprotected sex with many partners has always posed a health risk in terms of sexually transmitted diseases, but beginning in the mid-1990s the AIDS epidemic posed a new risk, particularly for men who have sex with other men. Kalichman et al. (1994) devised two types of SSS to study this group of men. The sexual sensation seeking scale (SSSS) items describe seeking intense sensation through sex although they are not specific to homosexual or heterosexual sex. The nonsexual experience seeking scale (NSES) is a GSS or ES scale with no reference to sex. Three high-risk behaviors were predicted using these scales: many sexual partners, anal sex without condoms, and the use of alcohol or drugs just prior to or during sex (Kalichman et al., 1994). The studies are summarized in Zuckerman (2007, Table 5.2: p. 161). In most studies both the SSSS and the NSES correlated with the three risk factors. In several other studies the General, Dis, and BS SSS also correlated with the three risk behaviors. The nonuse of condoms during anal sex is motivated by the need for more intense stimulation, and the need for many partners by the arousal produced by novelty. The use of alcohol before sex reduces inhibition by the awareness of risk and some drugs used during sex also enhance the intensity of arousal. Sensation seeking can be a deadly trait for those engaging in such risk-taking during sex. Drugs can themselves be a major reward in sensation seeking as next described.

Smoking, Drinking, and Drugs

Correlations among different types of risk-taking show a central intercorrelated core of smoking, drinking, drugs, and sex (Zuckerman and Kuhlman, 2000). The relation between sensation seeking and smoking was first studied by college students in the 1970s (Zuckerman, Tushup, and Finner). Since then the association has been replicated in American college students, the broader American population, Norwegian army recruits and high-school students, the Dutch general population, and Israeli adolescents (see Zuckerman, 1994, 2007, for descriptions of particular studies). Wider publicity on the serious health risks of smoking has reduced the overall incidence of smoking in the younger generations, but the relationship with sensation seeking persists from the 1970s to the present. Recognition of high sensations seekers, as those most involved in smoking, has guided those who design ads and interventions to prevent and discourage smoking in young adolescents (Donohew et al., 2004).

Several studies of preadolescents (ages 10–11) show that sensation seeking, as part of an undercontrolled, impulsive personality, predicts drinking in adolescent and young adult years. Sensation seeking is associated with early onset of drinking, frequency and quantity of drinking, binge drinking, alcohol abuse, and dependence. It is also associated with antisocial tendencies in alcoholics. Hittner and Swickert (2000) did a meta-analysis of 61 studies of the relationship between alcohol use and sensation seeking. The effect size for the SSS Total score was modest but highly significant, but the effect was highest for the Dis subscale ($r = 0.40$). There is a problem in confounding between some items in the Dis scale and reports of drinking but the effect size was the same in studies which removed these items and studies which did not do so (e.g., Finn and Hall, 2004). Studies using the ZKPQ ImpSS scale, which does not contain content confounding items, yielded an effect size as large as that for Dis in the SSS.

The relationship between personality traits and drinking may be mediated by motives for drinking. Cooper et al. (1995) developed a four-factor model for drinking motives: (1) social drinking (parties, celebrations); (2) coping (reduction of anxiety and depression in dealing with problems); (3) enhancement (increasing pleasure and excitement by getting 'high'); and (4) conformity (fitting in and being accepted and liked in a drinking group).

Sociability E is associated primarily with social motivation, N with coping, and sensation or excitement seeking to enhancement motives. Coping and enhancement are both related to heavy drinking but coping is more associated with drinking problems.

Alcohol and marijuana are the earliest and most widely used substances but because marijuana provides some novel sensations and experiences it is more widely used among high sensation seekers. Segal et al. (1980) studied substance use in large samples of college students and naval personnel. Among college students, marijuana users were higher on Dis and ES (confounding items removed from both) than both abstainers and those who used alcohol only but they were not different from those who used other drugs as well. Among the naval personnel, the major difference was between marijuana users and polydrug users rather than alcohol-only users. Later studies of college, community, and drug abusers show that sensation seeking is more related to the number of drugs used than to any specific drug.

Although heavy drinking and marijuana use are the most common forms of substance use and abuse, some high sensation seekers go on to harder drugs including stimulants (cocaine, amphetamine, methamphetamine), suppressants (morphine, opium, heroin, methadone, narcotics), and psychedelics (LSD, MDMA, or 'ecstasy'). Although the different classes of drug have different effects, all are related to sensation seeking as motive and trait (Zuckerman, 2012). Adams et al. (2003) found that NS (a scale highly correlated with ImpSS) was higher in stimulant users than in substance abusers who preferred sedatives such as opiates or narcotics. However it has been repeatedly shown that sensation seeking is more highly related to number of drugs used than specific drugs used. Stimulant use is more highly related to polydrug use than heroin use. However even heroin users value the 'rush,' a highly stimulant effect of the drug immediately after injection.

Sensation seeking predicts outcome of treatment in cocaine addiction (Ball, 1995; Patkar et al., 2004). High SSS is related to poor attendance, high dropout rates, and failed urine tests. Apparently treatment cannot supply a substitute for the positive arousal supplied by drugs. The use of psychedelics is related to the need for novel experience. The effects are different every time they are used and include hallucinatory-type experiences. Segal and Singer (1976) asked drug users about their motives for using particular drugs. Nearly three-quarters of LSD users said that they used the drug to provide a new experience. A fifth of the users said that they were motivated by curiosity. A large study in Europe found that ecstasy users were higher than nonusers on the ImpSS scale (Benschop et al., 2003).

Vocations

Firefighters tend to score high on the SSS. There are periodic periods of high excitement and risk in firefighting. Police and military personnel are average in sensation seeking but, as discussed previously, those among them who volunteer for highly risky jobs or engage in risky behavior like car pursuits are high sensation seekers.

Stressful work, even that not involving personal risk, seems to attract high sensation seekers but is aversive to low sensation seekers. Thus air-traffic controllers have periods of high stress when many flights are competing for space alternating with low activity periods (Musolino and Hershenson, 1977). There is a danger that their high BS during the nonstress periods could lead to inattention posing a risk for air-flight passengers. Medical personnel who choose to work in emergency rooms and rape crisis counselors also tend to score high on sensation seeking in jobs which are sometimes highly stressful.

Entertainment Preferences

Many choices of high sensation seekers have no risk but reflect the basic attraction to sensations and experiences (vicarious) that reflect their taste for novelty, intensity of sensation and arousal, and complexity (Zuckerman, 2006). In movies and television, and art and photography, they are attracted to erotic and violent content. In art they like expressionist, abstract, surreal styles, and even the surprise and humor of Pop art. They also need variety and are quickly bored as indicated by channel switching when watching television (Perse, 1996; Schierman and Rowland, 1985). In music, the high sensation seeker tends to favor the intensity of rock music. These preferences cross the auditory and visual arts. For instance, preferences for violent-abstract painting and hard rock music at one pole and realistic painting and 'easy-listening,' quiet melodic music at the other constitute a dimension related to sensation seeking, particularly disinhibition (Rawlings et al., 2000).

Biological Influences

In the first half of the twentieth century most personality theorists tended to attribute variance in personality traits to parental treatment of children and later life experiences. This bias in what came to be called the 'nature versus nurture' debate was not based upon research but reflected the psychodynamic influences among most theorists and their use of anecdotal, retrospective case history approaches. Behavior genetics, first applied in the area of intelligence, offered a statistical method for examining the relative influences of nature (genetic) and environment while holding the other constant. The method was largely based on comparisons of degrees of relationship between siblings within families. Twins are of particular value because identical twins share all of their genes whereas fraternal twins only share half of the genes that vary within populations, but both types of twins are presumed to share a similar family environment. This allows for a comparison of genetic influence controlling the influence of shared environment.

Genetics

Johnson et al. (2008) did a gigantic meta-analysis for over 50 years of biometric studies organized around the Big-Five trait classification (McCrae and Costa, 2003). There are three surprises in the results. One is the strong influence of genetics as given in the heritability estimates in the five major traits as calculated from studies of twins, whether raised together or adopted into different families and raised without contact during their formative years. Genetic influences account for nearly half of the total variance for most of the traits. The second is the weak influence of shared environment, including the shared family. Environment is important in the remaining part of the variance but it is the nonshared environment or experiences that specifically affect one of the twins and not the other. The third is the narrow range of

variation in results of studies. Some had suggested that some traits are primarily determined by genetics whereas others are primarily due to the family environment. The results showed a narrow range of variation in heritability of specific traits, between 40% and 50%.

In this context the heritability for sensation seeking lies at the high end of the range for personality traits for the total score on SSS-V heritability was 58% (Fulker et al., 1980). For twins adopted soon after birth and raised in different families without contact, the heritability was 59% (Hur and Bouchard, 1997; Lykken, personal communication, 1992). Since the twins were raised in different environments, the lack of difference in heritability indicates no evidence of an effect for shared environment, Eysenck (1983). Hur and Bouchard (1997) and Koopmans et al. (1995) analyzed the heritabilities of the subscales of the SSS-V. Across all three studies, the mean heritabilities for Dis, TAS, and ES ranged from 50% to 57%. BS was lower, 43%, probably because of the lower reliability of this subscale. Except for BS, the heritabilities of the subscales are close to those for the Total score.

Molecular Genetics is the study of specific gene variants. The evidence of moderate to high heritabilities for personality traits using the methods of behavior genetics suggested that it might be possible to find a few genes that were strongly related to each trait. No one expected only one gene to be related to each trait because the studies showed additive genetic effects for most traits.

The first successful study was an association between the trait of NS (highly related to sensation seeking, Zuckerman and Cloninger,1996) and the dopamine receptor 4 gene (DRD4, Ebstein et al., 1996). The DRD4 has two common variations in Western populations: a short form with four repeats of the base sequence and a long form with seven repeats. The long form was associated with high NS scores and the short form with low to moderate scores. Not all replications were successful. The most recent meta-analysis, including 48 studies published between 1996 and 2006, showed an association between both NS and extraversion and the DRD4 (Munafo et al., 2008). However another variant of the DRD4, the C-521T, was associated with NS and impulsivity but not with E. Apart from the problematic nature of the gene–trait association itself these gene variants only account for 3–4% of the trait variance. Obviously there must be many more genes involved and many may be of too small an effect to be detected.

Genes may determine specific behavioral traits rather than a broad measure like the trait ones we use as convenient summaries. The DRD4, for instance, has been associated with attention problems and sensation seeking behaviors in young children (Schmidt and Fox, 2002), attention deficit hyperactivity disorder (Faraone et al., 2001), and drug and alcohol use in young adults (Ebstein and Kotler, 2002). The A1 allele of the DRD2 dopamine receptor is found with greater frequency in alcohol, cocaine, and methamphetamine users (Noble, 1998).

The DRD4 has also been associated with sexual desire, function, and arousal (Ben-Zion et al., 2006). In primarily heterosexual and homosexual males, the DRD4 was associated with same-sex experience in the heterosexuals and opposite-sex experience in the homosexuals (Hamer, 2002). This could represent the attraction to novelty in sexual experience beyond that expressed in the variety of partners within the established sexual preference.

Biochemistry

The hormone testosterone is the driving force in sexual arousal in men. Given its absence or very low levels, sexual arousal is difficult. Daitzman and Zuckerman found that plasma testosterone was related to sensation seeking, particularly the disinhibition subscale. These findings were later replicated by Aluja and Garcia (2008), Aluja and Torrubia (2004), and Gerra et al. (2000), but not by Dabbs (2000), who used a salivary measure of the hormone. However investigators have found that testosterone is associated with a broader range of approach traits including extraversion, impulsiveness, assertiveness, rebelliousness, and aggression; it is also associated with the number of sexual partners. The evolutionary role of testosterone is demonstrated in a study of a polygynous culture that found that extraversion was related to high testosterone, polygynous marriage, and number of offspring in men (Alvergne et al., 2010).

Monoamine oxidase (MAO) is an enzyme that regulates the levels of monoamines in human and primate brain. It comes in two forms: type A preferentially oxidizes the neurotransmitters, serotonin and norepinephrine, whereas type B regulates brain dopamine (Shih et al., 1999). MAO-B can be obtained from blood platelets in humans although the relation between brain and platelet MAO is unknown. Many studies (9 out of 14) found a significant negative correlation between MAO-B and sensation seeking (Zuckerman, 1994). Low levels of MAO-B are also found in personality and clinical disorders characterized by impulsivity and sensation seeking such as antisocial personality disorder and bipolar mood disorder. Low levels are also found in those who abuse alcohol, tobacco, and drugs, all usually associated with high sensation seeking. All drugs, but particularly stimulant drugs, release the catecholamines, dopamine and norepinephrine in the brain.

Dellu et al. (1996) compared two strains of rats, one highly reactive to novelty (HR) and another low reactive (LR), or novelty avoidant, on self-administration of amphetamine and general exploratory behavior across a variety of situations. The HR rats self-administered amphetamine much more than the LR rats, were more exploratory, and autopsy showed higher levels of dopamine activity in the nucleus accumbens, a reward center in the brain where stimulant drugs have their major euphoric effects. In humans, dopamine is assessed indirectly through reactions of dopamine indices to dopamine stimulants like amphetamine. Studies relating sensation seeking to these indices have had mixed results. One problem with the studies of humans is that the measures of dopamine are not specific to brain areas. Dellu et al. (1996) found that dopamine in the nucleus accumbens correlated positively with exploratory behavior in rats but dopamine in the prefrontal cortex showed results in the opposite direction. Studies of responses to dopamine stimulants in relation to sensation seeking in humans have had mixed findings (e.g., Depue, 1995; Gerra et al., 2000; Netter et al., 1996; Wiesbeck et al., 1996). Brain imaging studies have showed a relation between sensation seeking

and amphetamine-stimulated arousal in the ventral striatum (containing the reward-sensitive nucleus accumbens) (Leyton et al., 2007; Stoops et al., 2007).

The biochemical theory of ImpSS suggests that the behavioral trait is based on an interaction between a HR dopamine approach system and an inhibition system based on serotonin (Zuckerman, 1995). Serotonin in limbic system pathways is generally associated with behavioral inhibition (Soubrie, 1986). Blunted serotonin reactivity to serotonin stimulants is characteristic in high sensation seekers (Depue, 1995; Hennig et al., 1998; Netter et al., 1996). Thus there is tentative emerging support for the biochemical/neurological theory of ImpSS.

Psychophysiology

The first biological theory was based on arousal and arousability of the cortical brain as regulated by the reticular activating system (Zuckerman, 1969). This is why the first studies focused on the electrophysiology of the brain at rest and in reaction to stimuli varying in novelty and/or intensity (Zuckerman, 1990). Studies of basal arousal levels of EEG, skin conductance, and heart rate showed no consistent differences between high and low sensation seekers in basal arousal, thus providing no evidence for a theory that high sensation seekers were chronically underaroused and needed intense or novel stimulation to reach an OLA.

However skin conductance and heart rate measures showed that high sensation seekers had a stronger response to a novel stimulus (orienting reflex) but not to subsequent repetitions of the stimulus to which they habituated at the same rate as low sensation seekers. These differences were enhanced by the emotional intensity and sensation seeking relevance of the content of textual stimuli. Novel and emotionally intense stimuli elicit a stronger autonomic response in high sensation seekers that is associated with positive affective tone.

The evoked cortical response is some function of stimulus intensity. However, the relationship between stimulus intensity and the amplitude of an early component of the EP has been shown to vary with sensation seeking, particularly disinhibition (Zuckerman, 1990; Zuckerman et al., 1974). The slope tends to be positive and strong in the high sensation seekers and weak or negative in the low sensation seekers. The results suggest some kind of cortical inhibition in response to high-intensity stimulation in the lows. The EP relationship to stimulus intensity is called 'augmenting' in the high sensation seekers and 'reducing' in the lows. Augmenting and reducing are also markers for similar behavioral characteristics in cats, such as approach to or avoidance of novel stimuli and impulsivity, or capacity to restrain response for reward (Saxton et al., 1987).

Evolution

Evolutionary psychology has been put forward as a new paradigm within which many or all fields of psychology, including personality, may be interpreted (Buss, 2009). But in fact there is a difference between personality and evolutionary theory. The former deals largely with individual variation within species and the latter with variation between species or subspecies. The former interprets variation at the more basic levels as expressive of genetic and biological variations and their influences in behavioral traits defining temperament. The latter assumes a genetic basis for evolved behavioral mechanisms but is less concerned with the specific genetic/biological bases for these differences.

I have postulated a possible evolutionary source for the trait of sensation seeking based not only on the adaptive value of behavioral component traits like explorativeness, sexual variety seeking, and risk-taking. But the evidence of evolution extends downward to other species, particularly those close on the evolutionary tree, like primates. However, mere similarity of behavioral traits across species leans too much on anthropomorphism unless we can show shared genetic/biological traits related to the similar behavioral traits within and between species.

Correlations between sensation seeking and behavioral traits have been found for hormones (testosterone), neurotransmitters, and their enzymes and controlling genes (dopamine, serotonin, MAO-B), and psychophysiological traits (EP augmenting/reducing), in humans and in monkeys, cats, rats, and mice. The findings suggest a broad trait of approach vs withdrawal, or sensation seeking vs. avoidance, or boldness vs. shyness, related to individual differences in most species of mammals, although it may even extend down to insects (Zuk, 2011). Of course these within-species differences are relative to between-species differences, such as that between predators and prey. Our hominid ancestors were both so that sensation seeking selection favored a balance between sensation seeking and avoidance. However of all the hominid species originally in Africa ours may have been the first to leave their familiar habitat to explore and settle in the furthest reaches of the world. Homo sapiens is a sensation seeking species, but one with a large range of variation in this trait within our species.

Abstract

The anthropology of the senses takes a cultural approach to the study of the senses, arguing that perception is a social as well as physical and psychological act. It explores the particular meanings associated with different senses and sensations across cultures and how these give rise to different sensory paradigms and practices for understanding and relating to the world. By so doing it challenges many of the assumptions and conclusions of Western sensory psychology (psychophysics) with regard to the number, nature, and uses of the senses. The anthropology of the senses has also been responsible for promoting a sensory approach to the study of culture. As a result, sensory reflexivity has become increasingly integral to good ethnography. Many domains can be explored and understood more fully when approached from a particular sensory or multisensory angle, including religion, medicine, material culture, kinship, apprenticeship, and even language.

The anthropology of the senses starts from the premise that the ways we use our senses, and the ways we create and understand the sensory world, are mediated by culture. Perception is, therefore, not only a matter of physical experience and personal associations, but also of social significance. The senses are constructed and lived differently in different cultures and historical periods. Hence, when we examine the meanings vested in various sensory faculties and sensations across cultures:

> we find a cornucopia of potent sensory symbolism. Sight may be linked to reason or to witchcraft, taste may be used as a metaphor for aesthetic discrimination or for sexual experience, an odor may signify sanctity or sin, political power or social exclusion. Together, these sensory meanings and values form the *sensory model* espoused by a society, according to which the members of that society 'make sense' of the world, or translate sensory perceptions and concepts into a particular 'worldview'. There will likely be challenges to this model from within the society – persons and groups who differ on certain sensory values – yet this model will provide the basic perceptual paradigm to be followed or resisted. (Classen, 1997: p.402)

The first task for the sensory anthropologist is accordingly to examine how the senses are fashioned in a particular culture, and to guard against projecting the sensory model of his or her own society (and class) onto the sensory life of the culture under study (Howes, 1991).

The Hierarchy of the Senses

The traditional Western sensory model holds that the senses are five in number, and that each sense has its proper sphere. Sight is concerned with colors, hearing with sound, smell with odors, and so on. The senses are also informally ranked, with sight being considered the 'highest' most informative, objective, rational, aesthetic, and 'civilized' of the senses. Sight is followed by hearing, 'the second sense.' Both sight and hearing are conventionally set off from the 'lower,' subjective, emotional, unaesthetic, and animalistic or 'brute' senses of smell and taste and touch.

The ranking of the senses is typically allied with the ranking of social groups. For example, the traditional Western association of the male sex with the 'higher' senses of sight and hearing supported the notion that men are naturally fitted for such activities as exploring, ruling, and studying or writing, while the association of the female sex with the proximity senses relegated women to the home, and made them mistresses of the kitchen, the nursery, and the bedroom. Such was the power of this categorization that those women who challenged the sensory division of labor (e.g., by writing or painting instead of cooking and sewing) faced considerable social opprobrium until well into the twentieth century (Classen, 1998).

As regards social class, the following description of French fishermen from a travel book of the 1920s illustrates how class may be sensed and the senses classed:

> [The fishermen] are strong, brown-skinned creatures, moving with a supple animal grace. Only a few have any ambition or education. Their life is primitive, hardworking, and simple, concerned with very little beyond the needs of food and shelter. (Peck, 1929: p.39)

The implication here is that the fishermen are like animals who, supposedly, live mostly through the lower senses, seeking food for their bellies and a warm place to sleep.

Another typical marker of class distinction is the capacity to distinguish between sensations within the same sensory register, and display a preference for those which are deemed to be more 'refined,' such as dark versus 'loud' colors in clothing, or haute cuisine versus 'greasy' fare in food (Bourdieu, 1984).

As regards race, the model of the five senses was used to categorize 'the five races of Man' in the grand taxonomy proposed by the German embryologist Lorenz Oken in the early nineteenth century:

1. The skin-man is the black, African.
2. The tongue-man is the brown, Australian-Malayan.
3. The nose-man is the red, American.
4. The ear-man is the yellow, Asiatic-Mongolian.
5. The eye-man is the white, European (Gould cited in Howes, 2009: p.10).

Oken's ascending scale of 'sensory perfection' (and skin pigmentation) was not based on any intrinsic propensities of the peoples concerned, but rather on their social ranking within the European imagination. His ostensibly biological categorization of senses and peoples was actually shot through with cultural values.

The senses continued to figure prominently in the ongoing effort to establish racial differences in the French physical anthropology and British psychological anthropology of the second half of the nineteenth century. One of the major issues debated by the members of the Société d'anthropologie de Paris (SAP), for example, was how the objectivity of racial categorization could be guaranteed if, as was assumed, perception is a physiological process and therefore potentially tainted with subjectivity? The 'solution' lay in exteriorizing the process of observation by (1) subjecting it to diverse protocols designed to neutralize the 'personal equation,' such as determining 'la bonne distance' from which to gauge the color of the iris (considered to be an essential marker of racial difference) and using Broca's chromatic scale to record judgments; and, (2) deploying a range of newly invented technologies (from the ophthalmoscope to the esthesiometer) which could substitute for the observer's own senses while objectifying those of the 'primitive' (Dias, 2004).

In addition to measuring the senses, the members of the SAP dedicated themselves to determining the localization of the various sensory and other faculties in the topography of the brain. The cultural hierarchy of the senses and its associated values clearly guided their research in this connection, as evidenced by the many fantastical observations they made (Dias, 2004).

The members of the 1898 Cambridge Anthropological Expedition to the Torres Strait (the first expedition of its kind) also employed a huge battery of tests – Zwaardemaker's olfactometer, Politzer's Hörmesser, Lovibund's tintometer, and so on – to gauge the sensory acuity of the natives. They did so based on the hypothesis that the senses (particularly the 'lower senses') of 'primitive man' would prove more acute than those of Europeans due to their mental inferiority and animalistic tendencies. The presumption that sensibility varied inversely with intelligence was a Eurocentric conceit of the first (and worst) order. The evidence of the tests was inconclusive but, astonishingly, this did little to unseat the hypothesis (Berry et al., 2011: ch. 9; Howes, 2012: 634–637).

It bears underlining that while some members of the expedition, most notably W.H.R. Rivers, entertained the notion that environmental (and not just physiological) factors might have a role to play in shaping the test results, no attempt was made to elicit the indigenous sensory model or study native perceptual practices.

From Measurement to Meaning

The critique and collapse of the concept of race in early twentieth century anthropology led to a corresponding decline in the explicit attention paid to the senses. This was due partly to the association of the study of the senses with the construction of the discredited racial taxonomies, and partly to the life of the senses having become the stuff of travel writing. Anthropology, which was striving to establish itself as a science, did not wish to be perceived as focused on 'superficial' sensations. Interestingly, one of the major critics of the racial hypothesis, Franz Boas, pointed to an alternate way forward for the study of the senses in a little note called 'Alternating Sounds' (Boas, 1889). This piece emphasized the importance of attending to the cultural patterning of sense impressions.

Boas' directive was finally operationalized in the 1950s when his former student, Margaret Mead, and various members of her circle, started to explore the notion that people "not only hear and speak and communicate through words, but also use all their senses in ways that are equally systematic … to taste and smell and to pattern their capacities to taste and smell, so that the traditional cuisine of a people can be as distinctive and as organized as a language" (Mead and Métraux in Howes, 2003: p.11). This promising opening was, however, overshadowed by the rise of language-based models of culture in the 1960s and 1970s (e.g., culture as language game, as discourse, as text), and the reduction of ethnography to writing in the 1980s. The 'writing culture' movement virtually obliterated the idea of sensing cultures. It did so by promoting 'the model of the text' (which compounded the logocentrism of conventional Western thought) and focusing attention exclusively on questions of interpretation, representation, authority, and style (Howes, 2003: ch. 1).

However, ongoing empirical research in cross-cultural psychology on such topics as color classification and susceptibility to pictorial illusions kept the senses from being entirely lost to view (Berry et al., 2011: ch. 9). The media theories of Marshall McLuhan and Walter Ong also had an influence, sensitizing anthropologists to the impact of different communications technologies on the 'balance' or 'ratio of the senses' (Carpenter, 1973; Howes 1991: ch. 11). The corporeal turn of the 1980s and 1990s, which highlighted the unity of mind and body (thereby deobjectifying perception), and promoted a more phenomenological approach to the study of cultural experience, was a further contributing factor with respect to bringing the senses back into focus.

As a result of the new emphasis on 'embodiment' (in place of 'representation'), anthropologists came increasingly to take stock of their own senses, and in the process discover things about the sensory models of the people they studied. For example, Paul Stoller underwent an acoustic epiphany in the course of his apprenticeship as a sorcerer among the Songhay of Niger. "You must learn how to hear, or you will learn little about our ways" (Stoller, [1984] 1989: ch. 7) his Songhay mentor admonished him following an incident where he sat there looking when he should have been listening. Stoller ([1984] 1989: ch. 1) also related how he was sensitized to Songhay gustatory codes after being served a particularly bad-tasting sauce by a disgruntled member of his host's household. He went on to write a discerning piece on the sauces of Songhayland, how they are distinguished on the basis of flavor and consistency, and how a cook can play with the ingredients to convey messages (Stoller, [1990] 2005).

While dramatic incidents of the sort Stoller relates may constitute a turning point for some, it is important to recognize that the conventional ethnographic method of 'participant observation' pioneered by Bronislaw Malinowski has always involved exercising the senses to some degree

(Howes, 2003). As François Laplantine observes in *Le social et le sensible*:

> The experience of fieldwork is an exercise in sharing the sensory world [*partage du sensible*]. We observe, we listen, we speak with others, we partake of their cuisine, we try to feel what they experience along with them. (Laplantine, 2005: p.11, my translation)

Good ethnography will therefore tend to be sensuous ethnography (Herzfeld, 2001). The anthropology of the senses itself, however, focuses on eliciting the sensory model of the culture (or subculture) under study and registering the full range of perceptual practices that underpin that model. This *cultural* approach is the complete opposite of the psychophysical approach of the 1898 Cambridge Expedition.

A Cultural Approach to the Study of the Senses

The enumeration, elaboration, socialization, and interrelation of the senses are four topics of interest to sensory anthropology. Taking a cultural approach to the study of these topics can reveal many issues which a psychological (including phenomenological) approach would miss or fail to comprehend adequately, as will be shown in the following.

Enumeration

Consider how the Cashinahua of Peru divide up the sensorium. They distinguish six sensoria or percipient centers – eyes, ears, skin, hands, genitals, and liver – and six kinds of sense-data or knowledge. 'Liver knowledge' pertains to the emotions, since it is in the liver that joy or sorrow, fear or hope, are felt. 'Ear knowledge' concerns social codes, perhaps reflecting the centrality of orality to the transmission of social values. 'Eye knowledge' has to do with perceiving the spiritual insides or substance of persons, animals, and things, as opposed to their surface. (This mode of perception, which is a characteristic of dreams is also helped by the ingestion of hallucinogens.) It is the skin that registers surfaces – the feel of the environment (including sun, wind, rain, and forest) and the behavior patterns of people and animals. 'Skin knowledge' is what enables the Cashinahua to navigate the jungle, locate prey, and interact with others.

'Hand knowledge' is divided by gender: in the case of women, the hands are the means by which knowledge of weaving, pottery-making, and cooking skills enter the body, while in men's case, the hands pick up how to hunt with bow and arrow or chop down a tree. 'Genital knowledge' has to do with sex and procreation, but more fundamentally it is bound up with awareness of mortality and immortality as embodied in one's children. Interestingly, when asked if the brain has any role to play in processing and retaining all this knowledge, the Cashinahua, while appreciating the question, thought not, rather 'the whole body knows' (Howes, 2009: p.2).

Cashinahua sensory psychology is fascinating for its denial of brain-based cognition and insistence on the modularity of the body, rather than of mind (Fodor, 1983). It also assorts functions rather differently than Western sensory psychology. For example, the Cashinahua treat emotions as perceptions in the case of 'liver knowledge' and also mix in sensori-motor functions with perception in the case of 'hand knowledge.' 'Ear knowledge' has a decidedly moral tinge to it since it has to do with conformity to social codes, and so cannot be considered strictly psychophysical either. Meanwhile, the Cashinahua appear to leave out taste and smell while attributing an exaggerated role to the skin and a very restricted role to vision. In effect, the Cashinahua feel with their skin what most Westerners would think of themselves as seeing with their eyes, and the Cashinahua see into places (e.g., the 'souls' of persons), which most Westerners would not think accessible to the senses.

These apparent exaggerations and diminutions, confusions and distinctions are all reciprocal, of course. There is no Archimedean point from which to determine how the senses function. The best an anthropologist can do is to cultivate the capacity to be 'of two sensoria' about things – their own and that of the culture under study (Howes, 2003: pp. 10–12).

If Western sensory psychology is to achieve more than parochial status, it will need to do the same as social anthropology, and acknowledge that there is no one true way to categorize the senses. W.H.R. Rivers, who played a key role in the professionalization of anthropology *and* experimental psychology in Britain in the early twentieth century, could have made a difference in this regard, if he had been more attentive to different ways of understanding the senses across cultures. Instead he assumed that the Western model provided the standard. Following his involvement with the 1898 Cambridge Expedition, he went on to conduct a series of psychophysical experiments among the Toda of India, and published the results in the first issue of the *British Journal of Psychology* (Rivers, 1905). Rivers never inquired into or tried to adapt his experiment to the Toda sensory model. Had he inquired he might have discovered a model that resembled the eightfold plan of the sensorium in the Brihadaranyaka Upanishad:

> (1) prana (breathing organ, i.e., nose; also 'breath of life'); (2) the speech organ; (3) tongue (taste); (4) eye (color); (5) ear (sounds); (6) mana (thought, mind, inner organ); (7) hands (work); and (7) skin (sense of touch). (Elberfeld, 2003: p. 483)

This model is noteworthy for its inclusion of mind and speech among the senses, as well as its privileging of olfaction (which has to do with breathing being the sense of reflection in India – e.g., in yoga – as sight is the sense of reflection in the West). But Rivers, set on his own sensory model, did not perceive any of this, and so the anthropological study of the senses remained dominated by Western biases for many decades to follow.

Elaboration

The anthropology of the senses is historically indebted to the phenomenology of perception. However, it departs from the latter by virtue of its focus on the 'performative elaboration' of the senses (Geurts, 2002: p. 5) as opposed to their 'phenomenological reduction' (Ingold and Howes, 2011).

Compare the experience of taste in, say, North America and India. Taste (*rasa*) is highly elaborated on multiple levels in the sensory model of Hindu India. The Sanskrit gustatory vocabulary consists of six terms, whereas the English taste lexicon has but four (five if one counts the Japanese loanword *umami)*. Ayurvedic medical theory recognizes a range of 'postdigestive tastes,' which suggest a prolongation of gustation and something much deeper than the experience of acid reflux or what in English are called aftertastes. Ayurvedic medicine also holds that the virtue of a medicine resides in its flavor whereas the taste of a drug is not counted among its therapeutic properties in contemporary Western medicine. Emotional states, of which there are eight according to the *Natyashastra*, are classified as savors in India whereas English-speakers assimilate them to 'feelings' and are more inclined to identify them by color (e.g., red with rage, green with envy, etc.). Audiences in India want to 'taste the rasa' of a performance, not just see a play or hear a concert, and there is (again) something more going on in this connection than what an English-speaker means by 'musical taste.' Taste differences are so important in India that they determine an individual's rank in the caste system (with its progressive vegetarianism) in contrast to the Anglo-American tendency to insist that meat be at the center of every meal. And not only is the social order grounded in dietary distinctions, but the very order of the universe is held to depend on regular gustatory exchanges between humans and gods. In the ritual practice of *prasad*, for example, one makes an offering of food to the deities and then, once the latter have consumed its essence or spirit, eats the leftovers (Pinard, 1991; Goswamy, 2005; Freeman, 2011). How would an English-speaking phenomenologist even begin to access any of these multiple senses of taste in India?

The phenomenologist would be on more familiar ground in the domain of sight. He or she could point out that sight is a spatial sense in contrast to hearing, which is temporal, that sight is a distance sense in contrast to touch, which is reciprocal, that sight fosters objectivity (the separation of subject and object) in contrast to taste, which involves fusion, and so on (Jonas, 1970). But then the whole edifice crumbles once cultural practice – the *performance* of the senses – is factored in. In the West, the gaze may appear to be unilateral and objectifying, but in India it is the *mutuality* of the gaze that is emphasized. The practice of *darsan*, for example, involves going to see and be seen by a deity in the form of an idol. This is understood to be auspicious rather than objectifying (Pinard, 1991).

The phenomenologist might carry on by suggesting that perhaps sight is a 'metaphorical touch' in India or, better, invoke the vision, which French phenomenologist Maurice Merleau-Ponty had toward the end of his life of the 'prereflective unity' of the senses and 'the flesh' as all-encompassing. However, while the senses might all come together in the consciousness of the individual subject, and so be thought to collaborate, they also conflict, as when a stick in water appears crooked to the eye but feels straight to the hand, or when a forest looks and sounds still and peaceful but the smell of a wolf signals danger. Cultural conflicts in sensation occur when, for example, a holy person considered to be ugly in appearance emits a sweet odor of sanctity (Classen et al., 1994). In fact, such conflicts happen all the time, albeit subtly (Stewart, 2007). Making sense of the world depends on attending to sensory differentials and breaking with the abstractions and essentialisms of phenomenology. (Many anthropologists identify as phenomenologists and think of themselves as doing phenomenology even when they have clearly had to slough off its strictures to make the observations they do. On the other hand, some do go on practicing phenomenology regardless.)

Socialization and Interrelation

In *Culture and the Senses*, Kathryn Geurts presents an in-depth study of how the socialization of the senses contributes to the development of the self, the acquisition of specific behavioral orientations, and the reproduction of cultural identity among the Ewe-speaking Anlo people of Ghana. This socialization begins even before birth with expectant parents picturing their unborn child as seated on a 'stool' in the womb (the stool being the placenta) practising the arts of posture and balance.

From the moment they can sit and hold their heads up without support, Anlo infants are implored to 'Balance! Balance!' A child's joints are continuously massaged, beginning with its first bath, to ensure agility of movement and inculcate a flexible attitude. As a minority ethnic group living in a resource poor region of Ghana, the Anlo-Ewe must be flexible. As one proverb puts it: "If you visit the village of the toads and you find them squatting, you must squat too" (Geurts, 2002: p. 96). In a related vein, the Ewe language contains over 50 terms for different kinaesthetic styles, or ways of walking, and these are used as a gauge of character. One wants to stride like a lion, *kadzakadza*, not meander, *lugulugu* (Geurts, 2002: p. 74)

The Ewe term for 'sense' is *seselelame* which, literally translated, means 'feel-hear feel-hear at flesh inside.' The audio-haptic connotations of this term, along with its accent on the interior milieu (interoception), reveal much about the focal sensory orientation of this culture. Interestingly, the Anlo hold that loss of hearing is the gravest form of sensory impairment, because with this loss would come a disruption to one's sense of balance. The maintenance of balance is key to what it means to be a person the Anlo way. And, when life gets out of balance, as happens more often than not, Anlo have a tendency to fold inwards, or curl up into a ball. This posture is captured in the very pronunciation of the word by which the Anlo designate themselves as people, and also refers to a particular moment in their migration history when the ancestor who led them out of slavery collapsed from exhaustion and despair. As one of Geurts' female informants noted, "being Anlo meant that you felt that way [i.e., rolled up] a lot, but you always had to unroll, or come out of it, and that gave you a feeling of strength" (Geurts, 2002: p. 118).

Parenthetically, balance is not normally counted as a sense in Western culture, and, on the whole, looks are more important than walks. Significantly, in many Western countries, expectant parents' first encounter with their unborn child usually comes in the form of an ultrasound image. If they are of a certain class, they may play Mozart recordings to the fetus.

The newborn child will continue to be exposed to Mozart and be entertained with colorful, geometric toys and Baby Einstein® videos while lying in its crib or other enclosure. The child's first book will likely be one of the countless childrens' books on *The Five Senses* which, by training the child to focus on the external (exteroceptive) senses and process each sensation separately, will have the effect of suppressing any interoceptive and/or synaesthetic tendencies it might have (van Campen, 2007). In the classroom, the child will be trained to sit still for long periods of time solely looking and listening. Resisting can only result in failure. The youth will go on to construct an identity for itself using social media.

A Sensory Approach to the Study of Culture

Geurts' work shows that exploring a given culture's sensory model – the ways in which the senses are discriminated, elaborated, and related to or combined with one another in practice – can illuminate many other aspects of the culture, such as its moral code and identity. This discovery underlines a point made by Constance Classen: "The broad range of applications for a sensory analysis of culture indicates that the anthropology of the senses need not be a 'sub-field' within anthropology, but may provide a fruitful perspective from which to examine many different anthropological concerns" (1997: p. 409). This point was picked up on and developed by Michael Herzfeld (2001), whose discussion in turn inspired the editors of *Ethnographic Fieldwork: An Anthropological Reader* to include a section on 'Sensorial Fieldwork' in their anthology. As they put it:

> sensorial fieldworkers [should] make the study of the entire sensorium indispensable to other domains of ethnographic inquiry, such as economics or politics … Just as attention to gender and reflexivity is now part and parcel of most ethnographic work, so the entire range of senses should be of similar concern. (Robben and Sluka, 2007: p. 388)

The fruits of this realization can be seen in the proliferation of sense-based methods of inquiry in anthropology, which both challenge and complement the language- or text-based models of earlier decades (Howes 1991: Epilogue; Feld, 2004; Bendix and Brenneis, 2005; Pink, 2009; Howes, 2012; Howes and Classen, 2013). For example, kinship studies, which used to be dominated by the analysis of kinship terminologies, has morphed into 'skinship' studies, which examines the sensory dimensions of the gestures by which kin relate to each other and distinguish themselves from nonkin (Gregory, 2011). Museum studies are increasingly centered on 'experiencing the [multiple sensory] properties of things' in place of 'contextualizing' them solely by means of labels or simply placing them on display (Lamp, 2004; Dudley, 2012). Food studies have transitioned from a concern with 'deciphering' a meal to an interest in how meals are 'experienced,' and how distinctions of flavor may structure social relations (Walmsley, 2005; Sutton, 2010). Religious studies are being rethought in the light of the notion of religions as 'sensational forms' (Meyer, 2009). Even anthropological linguistics has been sensualized as the old debates over how language 'determines' perception, have been supplemented by a new, more productive focus on the senses 'in' language (Classen, 1993: ch. 3; Majid and Levinson, 2011).

Some have called for the reconciliation of language- and sense-based approaches to culture (Porcello et al., 2010). This would be a welcome development, and there is precedent for it in the fact that many cultures treat speech as a sense (Howes, 2009: pp. 3–4). Perhaps therefore this opposition can be overcome. What of the other opposition touched on at various points in the preceding account – that is, the rift between sensory anthropology (with its openness to indigenous constructions of the sensorium) and Western sensory psychology (with its psychophysical reductionism)? The emergent field of neuroanthropology, with its notion of the 'encultured brain' (Lende and Downey, 2012) is one area where there could be a fruitful conversation between sensory anthropologists and their counterparts in the brain sciences. Here, though, it is important to bear in mind (and be prepared to answer) the Cashinahua's challenge to the cerebrocentrism of the latter approach.

By way of illustration, consider the Brazilian martial art of capoeira as described by Greg Downey, who is both a seasoned anthropologist and one of the leading scholars of neuroanthropology. In *Learning Capoeira* (2005) and other works, Downey relates how he was sensitized to diverse highly specific visual and auditory techniques and kinaesthetic practices in the course of his apprenticeship to a master capoerista. Capoeira is famous for the cunning subterfuges, lightning-quick strikes, and extraordinary feats of balancing while upended (i.e., imbalanced) displayed by its adepts. Success at fending off attacks depends on cultivating what is known as the 'sideways glance' – that is, on the practitioner dispersing his or her attention over the entire visual field and suppressing the natural reflex tendency to visually track moving objects or actions. This is a fascinating example of how 'culture tunes our neurons' (Sacks quoted in Howes, 2005: p. 21) or, in other words, how cultural practice overwrites the way the brain is wired, since our natural tendency is to track objects and movements with our eyes. Downey elaborates on what this technique of perception involves:

> A practitioner must pay careful attention to the whole body of his or her adversary all at once because some capoeiristas practice movements that are disjointed. Rather than being grounded in the cooperative action of the entire body, movements involve only a single part in isolation, making it very hard to anticipate what will happen from observing other body parts; that way attacks can also be thrown from unforeseen angles. (Downey, 2007: p. 229)

The phenomenologist would be flummoxed by this description, but the Cashinahua might just find it of interest, given the parallels to their own theory of the modularity of the sentient body.

Abstract

The study of sentence comprehension focuses on how listeners and readers, guided by their knowledge of the grammar of their language, map recognized words onto the meanings of sentences. Psycholinguists have developed offline and online tasks for studying how listeners and readers comprehend sentences. This article reviews some of these tasks and some of the phenomena they have identified, including immediacy, structure-sensitivity, ambiguity resolution, lexical and frequency effects, and the effects of context and prosody. It outlines some of the theories that have been developed to account for these phenomena, and concludes by discussing some phenomena of how sentences are comprehended in realistic contexts.

Comprehending sentences is a process of mapping form (speech or printed text) onto sentence meaning. This article examines the cognitive challenges posed by this process, describes some experimental techniques that psycholinguists have used to understand it, summarizes some basic empirical phenomena and theories of how people identify the structural relations among words in a sentence (how sentences are 'parsed'), and concludes by discussing how sentences are interpreted in context.

The Tasks of Sentence Comprehension

Words are stored as units in lexical memory, but there are just too many sentences for there to be a 'lexicon' of sentences. A reader or listener has to construct or 'compose' the meaning of a sentence out of the meanings of the words in it, constrained by their grammatical relationships. Sentences, that is, must be built compositionally. This compositional process maps seemingly small differences in wording onto very large differences in meaning: Consider the sharp contrast between *The man helped the child to first base* and *The man helped the child on first base*. Listeners and readers also go beyond identifying the grammatical structure of a sentence and the meaning that it explicitly supports, and identify some of the propositions it implies. Social knowledge and knowledge about the world can guide such inferences. If you read *The man paid for the car*, you probably infer that he owns it; if you read *The man paid for the room*, you do not make the same inference. And if you hear someone say *Could you close that window* you recognize it as a request, not as a question about your abilities.

The task of mapping from print or sound to meaning begins with recognizing words, which is by itself not a simple task (*see* Visual Word Recognition, Neurocognitive Psychology of). The information that is retrieved when a word is identified makes an important contribution to sentence meaning (consider the difference between *to* and *on* in the example from the previous paragraph). Another example is the contrast between *Tom gave his dog biscuits* and *Tom gave him dog biscuits*. The difference between *his* and *him* signals a difference in the 'case' of the pronoun, an aspect of its morphology that carries information about the relation it has to a verb or some other 'case-assigning' word in a sentence. The form *him* signals accusative case, which means that the pronoun has some immediate relation to the verb, in this case the indirect object or 'recipient' of the action denoted by the verb. The form *his*, on the other hand, signals possessive or 'genitive' case, which means that the pronoun is immediately related to the following noun *dog*. This whole noun phrase *his dog* in turn takes the recipient role. (Actually, some ambiguity still remains: the larger noun phrase *his dog biscuits* could be the direct object, playing the role of 'theme,' with the recipient unspecified. Listeners and readers are often unaware of ambiguities like this.) Morphologically signaled case actually plays a minor role in English, although it plays a very important role in many other languages. Languages like English signal the structural relations between their words primarily by word order (compare *The dog bit the man* and *The man bit the dog*),

The task faced by listeners and readers is made particularly challenging by the ubiquitous ambiguity of language. Ambiguity begins in the speech stream, which often can be segmented at different points into different words (*see* Speech Perception; see also Cutler et al., 1997). A given word form can correspond to different lexical concepts (e.g., the word *bank* may refer to either a financial institution dealing with money or to a river bank). And a string of words can exhibit different structural relations, which may or may not be resolved by the end of a sentence. (When the ambiguity is resolved by the end of the sentence, the ambiguity is 'temporary'; sometimes the ambiguity is not resolved, although the reader or listener may not realize that it remains.) For instance, *I understood the article on word recognition was written by a real expert* has a temporary ambiguity. Listeners' and readers' knowledge of syntax (roughly, the hierarchical relations among words and phrases in a sentence) allows them to take *article on word recognition* to be either the subject of a complement sentence (…*was written by a real expert*) or (at least temporarily) the direct object of the verb *understood*. (If you have any trouble understanding this sample sentence, try adding the complementizer *that* right after *understood*.) Listeners and readers are generally not aware of such ambiguities (although puns force awareness; consider *A will is a dead giveaway*), but that only means that people's cognitive processes adequately resolve the ambiguities in the course of sentence comprehension. Studying how ambiguities are resolved has shed a good deal of light on these cognitive processes (see Section Phenomena of Sentence Comprehension, below).

Listeners' and readers' understanding of a sentence is guided not only by their knowledge of the words it contains but also by the morphology and syntax of their language. (Morphology is the structure of word forms, including the morphemes that determine word meaning plus morphemes that signal part of speech and various linguistic features, e.g., tense and number; syntax refers to the hierarchical relationships among the words and phrases of a sentence, or in other words, how linguistic elements such as words are put together to form constituents such as phrases or clauses.) Discourse context and world knowledge also affect comprehension. For instance, *I want the flowers on the table* means one thing if it is the answer to the question *Where do you want the flowers?* and something quite different if it answers *Which flowers do you want?* The context guides whether *on the table* is syntactically related to *want* or to *the flowers*.

Ways of Studying Sentence Comprehension

Offline Techniques

When psycholinguistics (a field that includes the study of the processes of sentence comprehension) was in its infancy, experimental techniques were largely limited to 'offline' techniques such as what is remembered when a sentence is comprehended (Miller, 1962). (Offline tasks gather information about the products of sentence comprehension, e.g., what remains in memory after a sentence is heard or read; online tasks measure real-time aspects of the process of sentence comprehension, e.g., how fast a particular word is comprehended.) These techniques did uncover some interesting phenomena, e.g., grammatical structure predicts which sentences will be confused in memory, and continue to do so.

One simple offline technique involves having speakers of a language make judgments about the acceptability of candidate sentences. They are typically asked something like, *Is this something that a competent speaker of your language would say*, or, *Is this something you can understand easily?* This is a version of what linguists typically do in their armchairs – make judgments about whether a sentence is good or not, in deciding whether the grammars they write should permit ('generate') the sentence. However, in the hands of experimental linguists and psycholinguists, acceptability judgments can be collected using proper experimental techniques such as controlling and counterbalancing sentence content, using subjects whose judgments are not confounded by their theoretical positions, and obtaining data whose stability can be evaluated using statistical methods (Cowart, 1997). These days, such judgments can even be collected quickly and easily from large numbers of participants using the Internet. Acceptability judgment experiments have supported interesting claims. For instance, Arregui et al. (2006) showed that elliptical sentences that violate a grammatical constraint that the elided material must match the form of its antecedent became more acceptable if the speaker was more likely to have misremembered the antecedent's form. For instance, people more often misremember passive sentences as active than vice versa (Mehler, 1963). Accordingly, they find a sentence like *Mary was scolded by her father, and today her mother did too* to be more acceptable than *Mary's father scolded her, and today her sister was too*. It appears that a listener or reader is more willing to accept a sentence that violates his or her knowledge of grammar if it seems likely that the speaker or writer could have made a mistake that led to the violation.

Various other offline techniques have been used. Some are as simple as asking for interpretations of ambiguous sentences. For instance, one can study how the prosody of a sentence (its rhythm and melody) affects its interpretation. Placing a prosodic boundary (a change in pitch together with lengthening and even a pause) at different points in a sentence can change its syntactic analysis, and if there are multiple prosodic boundaries, their relative sizes matter. For instance, Clifton et al. (2002) played listeners' versions of discourses like *Who arrived? Johnny and Sharon's in-laws* with prosodic boundaries after *Johnny* and after *Sharon's*. When the boundary after *Johnny* was larger than that after *Sharon's*, people said it was Sharon's in-laws and Johnny who came; when it was the same size or smaller, people said Johnny's and Sharon's in-laws came. The long tradition of studying what is remembered from sentences continues to provide useful information (e.g., about how memory for material that is focused – generally informative material, which can be prosodically marked – is enhanced).

Online Reading Techniques

Sentence comprehension seems almost effortless and automatic, but is really a very complex process. Psycholinguists have devised 'online tasks' to probe into the fine-grain details of this smoothly flowing process. Some early psycholinguists used a technique of sentence verification, measuring the time taken to decide whether a sentence was true or false (e.g., when spoken of a picture). Others (e.g., Mitchell, 1984) measured the time readers took to read each word or phrase of a sentence when sentence presentation was under their control (pressing a button brings on each new word), thereby getting a more precise look at the difficulty readers experience word-by-word. Pressing buttons to read word-by-word is not a highly developed and natural skill and may disrupt normal reading processes. However, the development of techniques for measuring eye movements during reading (Rayner et al., 1989; *see also* Eye Movements in Reading) overcame this objection and, together with the self-paced reading technique, has provided very illuminating data about language comprehension (Clifton et al., 2007).

Online Listening Techniques

Psycholinguists have also developed ways of measuring the process of comprehending sentences during listening. One very useful technique measures event-related brain potentials, electrical traces of underlying brain activities measured at the scalp (*see* Cognitive Neuroscience) at critical points in sentences, e.g., when a sentence becomes implausible or ungrammatical or simply difficult to process. There appear to be distinct signatures of different types of comprehension disruption. For instance, implausibility or violation of expectations commonly leads to an 'N400,' a negative-going voltage shift that peaks about 400 ms after the introduction of the implausibility. This allows a researcher to test theories about

just when and how disruption will appear in hearing or reading a sentence. Another illuminating technique (the 'visual world' technique) relies on the fact that people tend to look at what is being talked about. Researchers have used this fact to study such phenomena as the time course with which sentences are interpreted by presenting subjects with displays of objects and seeing where they look as they hear a sentence (Tanenhaus and Trueswell, 2006).

Phenomena of Sentence Comprehension

Immediacy

Early theories of processing, guided by linguistic analyses that posited 'transformational' rules whose domain could be as large as a full clause, proposed that full sentence analysis and interpretation took place only at a clause boundary. These theories were supported by evidence that memory for verbatim information declines across a clause boundary, that clauses resist interruption by extraneous sounds, and that readers pause at ends of clauses and sentences to engage in 'wrap-up' processes (Fodor et al., 1974). However, a great deal of evidence now exists indicating that readers do substantial interpretation on a word-by-word basis, without waiting for a clause boundary. The initial evidence for this claim came from Marslen-Wilson's (1973) work on 'fast shadowing' (repeating what one hears, with no more than a quarter-second delay). He showed that if the shadowed message contained a mispronunciation of a word's end (e.g., *cigareppe*, where *cigarette* is expected), the shadower would fairly often correct it spontaneously. As this happened more often in normal than in scrambled sentences, the listener must be using grammatical structure or meaning within a quarter-second or so to constrain recognition of words.

Evidence from measuring eye movements in reading led to a similar conclusion (*see* Eye Movements in Reading). For instance, if a person reads *While Mary was mending the sock fell off her lap*, the reader's eyes are likely to fixate a long time on the word *fell* or to regress from that word to an earlier point in the sentence. This happens because the verb *fell* is grammatically inconsistent with the normally preferred structural analysis of … *mending the sock*; *the sock* must be the subject of *fell*, not the object of *mending*. Sentence meaning is also processed on a nearly word-by-word basis. Eye movements are disrupted immediately upon reading the anomalous *carrots* in a sentence like *John used a pump to inflate the large carrots last night*. This pattern of results indicates that readers (and presumably listeners) create and evaluate grammatical and meaning relations word-by-word, without waiting for a clause boundary.

It is tempting to hypothesize that listeners and readers always perform a full semantic analysis of sentences word-by-word, without ever delaying this analysis. This 'immediacy hypothesis' may be too strong. Some evidence indicates that, while true lexical ambiguities (e.g., the difference between bank of a river and bank for money) may be resolved word-by-word, sense ambiguities (e.g., the difference between newspaper as something to read and newspaper as an institution) may not be. Similarly, determining the antecedent of a pronoun may be a task that readers do not always complete at the first opportunity. Nonetheless, one secure conclusion is that listeners and readers generally understand a great deal of what a sentence conveys with little or no lag.

Structure Sensitivity

Words are identified almost immediately as they are heard or read, but that is not the end of comprehension. The relations among words are identified almost immediately, constrained by the reader or listener's knowledge of linguistic structure as well as by the discourse context. These structural relations then constrain the possible meanings of a sentence or sentence fragment. The fragment *I understood the article on word recognition* … means one thing if *the article* is taken as the grammatical direct object of *understood*, and something quite different if it is taken as the subject of a new clause (the 'sentential complement' of *understood*).

Many psycholinguists have taken the generative grammars that have been developed following Chomsky (1957) as useful descriptions of the grammatical knowledge that listeners and readers use in identifying sentence structures. One important structure is phrase structure, the division of a sentence into its hierarchically arranged phrases and the labeling of these phrases. For example, *I understood the article on word recognition was written by an expert* is divided into the subject *I* and the verb phrase *understood … expert*; this verb phrase is divided into the verb *understood* and its embedded sentence complement *the article … was written by an expert*; this sentence is similarly divided into subject and verb phrase; etc. Another aspect of structure is the long-distance dependency between 'moved items' or 'fillers' and their 'traces' or 'gaps' (as in the relation between a *which*-phrase and its source, in *Which article did you just read t*, where the *t* stands for the 'trace' of *Which article*). Still other structures involve case relations (e.g., the distinction between accusative and genitive case discussed earlier) and thematic role relations (e.g., the distinction between theme or affected object and recipient in the sentence *Tom gave his dog biscuits*).

Early psycholinguists devoted much attention to the 'psychological reality' of grammatical structures, arguing whether they are really involved in sentence comprehension (Fodor et al., 1974). As psycholinguistic theory developed, it became apparent that the real debate involves not whether these structures are real but how they are identified in the course of sentence comprehension and how, in detail, the mind creates and represents them. It now seems impossible to explain how we understand sentences without theorizing about how people assign structure to sentences. However, as we will see later, there is very lively debate about just how they do identify sentence structure.

Ambiguity Resolution

Many sentences contain ambiguities, temporary or permanent. Listeners and readers are often not aware of them. They seem to use context, knowledge of the speaker or writer, etc., to arrive at a sensible interpretation. But sometimes readers make the wrong interpretation of an ambiguity, and find themselves confused when they realize their error. They are said to have been 'led down the garden path' by the sentence (Frazier, 1987). (In psycholinguistics, 'led down the garden path'

refers to a phenomenon in which incorrect structural relations are assigned, sometimes temporarily, to the words and phrases of a sentence; the term comes from Victorian novels, where the villain leads the innocent young thing 'down the garden path.') A classic example of a garden-path sentence is *The horse raced past the barn fell*. This sentence is nearly incomprehensible; the reader initially takes *raced* to be the main verb, with *The horse* as its subject, but really *the horse* has to be the object of the passive participle *raced*. The sentence is not actually impossible; it is basically just like *The car driven over the cliff exploded*, which lacks the garden path and is easy to comprehend.

The mistakes listeners and readers make can be extremely diagnostic of the decision rules they follow. A simple empirical generalization (which may or may not describe the cognitive process a reader or listener is engaging in; see Section Psychological Models of Sentence Comprehension) is that when a choice between two analyses has to be made, the reader/listener initially favors (1) the choice that is simpler in terms of grammatical structure, or (2) in the absence of complexity differences, the choice that permits new material to be related to the most recently processed old material. In a sentence like *I knew the answer was wrong*, the direct object analysis (… *knew the answer*) is grammatically simpler than the sentence complement analysis (… *knew the answer was wrong*). In the sentence *While Mary was mending the sock fell off her lap*, a reader/listener prefers to relate *the sock* to the recently processed verb *mending* rather than to material that has not yet been received. In both cases, these preferences are disconfirmed by material that follows, resulting in a garden path.

A great deal of experimental work using techniques described earlier has indicated that reading is disrupted and distinctive patterns of scalp electrical potentials are observed at points where garden paths occur. Not all these garden paths are apparent to conscious introspection, but they can be observed experimentally. Normally, the rules listeners and readers use to decide on the grammatical structures of sentences function so smoothly that their operation cannot be observed. But just as the analysis of visual illusions allows insight into the normal processes of visual perception by identifying when they go astray, identifying when a rule for analyzing sentence structure gives the wrong answer can go far in determining what rule is actually being followed.

Lexical and Frequency Effects

The relations among words and phrases that a reader or listener must identify to comprehend a sentence are specified by the grammatical principles of a language, but individual words contain a great deal of grammatically relevant information. The difficulty, and possibly even existence, of garden paths are modulated by properties of the words in a sentence. For instance, the normal preference to take a noun phrase following a verb as its direct object (which leads to difficulty in sentences like *I understood the article on word recognition was written by an expert*) is reduced for verbs that are more often used with sentence complements than with direct objects. A similar phenomenon can be observed for the much-studied ambiguity between a main verb and a reduced relative clause analysis. Consider the sentence fragment *The patient examined* … A reader who analyzes this fragment in the most straightforward way, as subject + main verb, will have been led down the garden path if it continues … *by the doctor*. Such a continuation indicates that *examined* really began a reduced relative clause that modifies *the patient*, so *examined* was not the main verb of the sentence. (If you have trouble with that, put *who was* before *examined*.) The difficulty of such sentences is reduced when the verb is one that strongly requires a direct object. Compare *The dictator captured in the coup was hated* with *The dictator fought in the coup was hated*; the former is easier, presumably because *capture* requires a direct object.

Plausibility and frequency of use also matter. Sentences that contain a temporary main verb versus reduced relative clause ambiguity are easier to understand when the subject is implausible as agent of the first verb but plausible as its theme are easier than sentences in which the subject is a plausible agent (e.g., *The evidence examined by the lawyer was unreliable* is easier than *The defendant examined by the lawyer was unreliable*). (However, this difference in difficulty of comprehension remains when the sentences are made unambiguous by adding *who was*, suggesting that the effect of plausibility should not be attributed to how it blocks the syntactic misanalysis.) Similarly, more frequent constructions are easier to comprehend. For example, if a verb is used relatively frequently as a participle as compared with its use as a simple past tense, the difficulty of the main verb/reduced relative clause garden path is reduced. MacDonald et al. (1994) reviewed these findings and spelled out one theoretical interpretation, which will be considered shortly.

Effects of Context

Sentences are normally not interpreted in isolation, which raises the question of how context can affect the processes by which they are understood. Some researchers have argued that normally observed garden paths could be eliminated when they are not supported by the situational context in which they are heard. Evidence supporting this has come from experiments using the 'visual world' technique (briefly described in Section Online Listening Techniques). Listeners hear an instruction like *Put the apple on the towel into the box* while they are looking at a display of objects. When there is one apple on a towel, an empty towel, and a box, they look first to the apple and then to the towel (and then follow the instruction). But if there are two apples (one of which is on a towel), an empty towel, and a box, they look just at the apple on the towel and not at the empty towel. The existence of the two apples apparently induced the listener to take the phrase *on the towel* as modifying *the apple* and not as an argument of the verb *put* (which is the normally preferred analysis).

Effects of Prosody

Spoken sentences carry one kind of information that is not well represented in print, the prosody (rhythm and melody) of a sentence. Prosody demonstrably influences how a sentence is comprehended. The presence of a prosodic boundary can affect the interpretation of a sentence. It can even eliminate the normal preferences that result in garden paths. For example the proper pattern of prosodic boundaries (including a boundary

after *studied*) can eliminate the normal difficulty of sentences like *Because John studied the material is clearer now* (in which *the material* is taken as the direct object of *studied*). However, there is more to prosody than just putting in pauses. The entire prosodic pattern of an utterance (including the relative size of prosodic boundaries, and the presence and location of points of intonational prominence called 'pitch accents') can affect how it is interpreted (Frazier et al., 2006).

Psychological Models of Sentence Comprehension

Psycholinguists have learned a great deal about the phenomena of sentence comprehension. This does not mean that they agree about the cognitive processes of listeners and readers that produce these phenomena. Early theories of how people understand sentences claimed that the rules that make up a linguistic theory of a language are known (implicitly) to language users, who use the rules directly in comprehending language (see Fodor et al., 1974). This did not work with the rules provided by early transformational grammars. Their rules operated on domains as large as a clause, and it soon became clear that people did not wait for the end of a clause to understand a sentence.

These early direct incorporation theories were replaced by what can be called 'detective style' theories (Clark and Clark, 1977). Listeners and readers were presumed to search for clues of any kind to the relations among words in a sentence. Psycholinguistic theorizing became little more than listing 'cues' that people used.

In the 1970s, a new breed of grammar-based theories developed. These theories added descriptions of decision strategies to the claim that people use the rules provided by the grammar, focusing on how they choose among various alternative rules in analyzing a sentence (Frazier, 1987; cf Frazier and Clifton, 1996; Mitchell, 1994; for further discussion of these theories). They claimed, for instance, that listeners and readers incorporate each new word into a sentence structure in the simplest and quickest possible way. This led to compelling accounts of garden-path phenomena, and the theories under discussion are often referred to as 'garden-path' theories.

In the 1970s and 1980s, linguistic theory moved away from positing broad, generally applicable rules to making claims about information contained in individual lexical items (constrained by some extremely broad general principles). This encouraged the development of 'lexicalist' theories of sentence comprehension (see MacDonald et al., (1994); for the most completely developed statement of such a theory). These theories emphasize the specific contribution of individual words rather than the effects of conformity to generally applicable word configurations. An individual word can provide a variety of kinds of information, including the possible and preferred thematic roles for its arguments, the frequency with which it is used in various constructions, and the entities it can refer to, as well as information about the phrase structure configurations it can appear in. Lexicalist theories propose that all these kinds of information are available and are used in deciding among alternative analyses.

Contemporary theories of sentence comprehension differ in the range of information that, they claim, guides sentence analysis. Garden-path theories are 'modular' in that they claim that only certain necessarily relevant types of information affect initial decisions about sentence structure. Lexicalist theories are generally nonmodular in allowing many different kinds of information to affect these decisions, and are often cast as constraint-based connectionist models in which all sorts of information (grammatical, lexical, contextual, world knowledge, etc.) contribute simultaneously to sentence comprehension.

Garden-path theories explain garden paths elegantly, and provide a more adequate account of how sentence structures are created than lexicalist theories do. On the other hand, they are forced to ascribe the effects of lexical structure, frequency, and context described above to a 'reanalysis' stage, which follows discovery that the initially preferred analysis is incorrect (see Fodor and Ferreira, 1998). Lexicalist theories, on the other hand, can provide a natural account of effects of lexical structure, frequency, and context, and are widely accepted in the psycholinguistic community. But they have not yet been developed in a way that adequately explains where sentence structures come from (it is unappealing to say that large parts of the grammar are stored with each lexical entry) or that explains why structurally complex sentences are overwhelmingly the ones that lead to garden paths (see Clifton and Staub, 2008; for some further criticisms).

Recent years have seen the emergence of 'memory-based' and 'statistical' models of language comprehension. The former (e.g., Lewis and Vasishth, 2005) apply basic principles of short-term memory to how sentences are comprehended. The latter (e.g., Levy, 2008) claim that listeners and readers form word-by-word expectations of upcoming sentence structure, based on the frequency with which they have experienced different structures in different contexts. Sentence comprehension goes more smoothly when a sentence structure is relatively strongly expected than when an unexpected structure is encountered. In some instances, these models have been implemented computationally, and are able to simulate many of the phenomena described above.

Interpretation

This article has focused on how listeners and readers use their knowledge of language to compose sentence meanings from words. While much of the power of language comes from listeners' and readers' abilities to 'follow the rules' and arrive at grammatically licensed interpretations of sentences, it is also clear that people are influenced by the discourse in which the sentence appears. Sentences are understood easily when they fit well into a discourse (e.g., when they accurately signal what is new to the discourse vs. what is old, or when they address a question that was raised implicitly or explicitly by prior discourse). The context in which an utterance is heard or a sentence is read can profoundly influence its interpretation. The meaning of words can be altered depending on the context in which they occur (consider *bank* in the context of a trip to the river to fish vs. a purchase of a house, or *red* in the context of a fire truck vs. a red-haired woman). A listener can determine whether a speaker who says *Can you open this door?* is asking about the adequacy of a job of carpentry versus requesting some

assistance. Speakers can rely on listeners to get their drift when they use figurative language such as metaphors and possibly irony (*My copy editor is a butcher*). And very generally, what a listener or reader takes a speaker or writer to mean may depend on their shared goals and mutual knowledge (cf Clark, 1996). Still, all these varied phenomena of interpretation depend on the listener's/reader's ability to put words together into sentence meanings, which makes the study of the topics considered in this article an important branch of cognitive psychology.

Abstract

Many scholars have examined sentencing disparities in efforts to explain why and how these differences occur and untangle the legal and extralegal influences on punishment. This article provides an overview of the common criminological perspectives found in the sentencing literature. We then summarize trends in sentencing research over the last three decades, reviewing much of the empirical research on disparities in the areas of race and ethnicity, gender, and mode of conviction. We conclude with a discussion of some of the gaps and unexplored/underexplored areas in the literature, making suggestions for future research in this field.

Introduction

A growing volume of research examines the determinants of criminal punishment and the degree to which differences in sentencing outcomes across types of offenders are legitimate. While there is no objective standard for deciding what constitutes warranted or unwarranted disparity, some differences in sentencing can be considered legally defensible. Many would agree that certain offenses are more serious than others, and that presence of aggravating or mitigating circumstances or other unique aspects of crimes may signal that relatively more or less severe penalties are appropriate. However, the extent to which sentencing disparities are unjustified is an area of considerable scholarly inquiry, and some dissimilarities, such as those related to offender demographic characteristics or mode of conviction, are particularly controversial. Many scholars have examined sentencing disparities in efforts to explain why and how these differences occur and untangle the legal and extralegal influences on punishment. This article provides an overview of the common criminological perspectives found in the sentencing literature. We then summarize trends in sentencing research over the last three decades, reviewing much of the empirical research on disparities in the areas of race and ethnicity, gender, and mode of conviction. We conclude with a discussion of some of the gaps and unexplored/underexplored areas in the literature, making suggestions for future research in this field.

Theoretical Perspectives on Sentencing

Explanations of sentencing can be classified across three general themes: court communities, focal concerns, and organizational efficiency. Although we discuss each separately, we do not mean to imply that these ideas are contradictory. Rather, they may be more appropriately considered as complementary. Although different aspects of the sentencing process are their particular focus, they may well lead to similar or consistent predictions regarding sentencing outcomes. First, the *court community perspective* argues that sentencing and sentencing disparity cannot be understood without taking into account local courts' organizational structure, organizational culture, case-processing strategies, and relationship networks. Research utilizing this approach focuses on the interactional dynamics of courtroom workgroups, conceptualizing courts as networks of action and communication based on participants' common working environment, interdependencies between key stakeholders (typically the prosecutor's office, bench, and defense bar) and local legal and organizational culture. Several scholars follow this theme, emphasizing the role of social contexts of courts and their decision-making processes (for example, see Eisenstein et al. (1988), Savelsberg (1992), Dixon (1995), Ulmer (1997), and Ulmer and Kramer (1998)). They view sentencing disparities as a product of the informal practices and negotiations among court communities, as well as formal policies and legal structures.

Other researchers have expanded on ideas that are compatible with the court community perspective. For example, Savelsberg (1992) discusses how the 'substantive rationality' of local contexts and individual interests, philosophies, and biases may be act to undermine formally rational decision-making criteria like sentencing guidelines. This may be particularly likely to occur when criteria have been externally imposed on local arenas and individuals. These local substantive interests potentially produce variation in the degree and type of sentencing disparity. Similarly, Dixon's (1995) 'organizational context' theory incorporates the court community perspective and extends on its themes. She emphasizes factors such as the bureaucratization of prosecutors' offices and the judges' bench as variables that exert particular influence on sentencing and sentencing disparity, even under sentencing guidelines.

Second, the *focal concerns perspective* is viewed as extension of the court community approach. Focal concerns explanations (Steffensmeier et al., 1998; Steffensmeier and Demuth, 2000) conceptualize sentencing as a process that occurs within the framework of uncertainty, as court decision-makers formulate attributions about offenders and crimes and act to balance practical and safety concerns. The focal concerns perspective is consistent with Albonetti's (1991) 'uncertainty avoidance' and causal attribution explanations of sentencing and court decision-making in that both highlight the uncertainty and insufficient information regarding the recidivism risk and rehabilitative potential of offenders. Albonetti (1991) describes

sentencing as a situation of bounded rationality in which court actors make highly consequential decisions with insufficient information. Drawing from attribution theory in social psychology, she argues that, as a means of reducing uncertainty, decision-makers fall back on attributions about reoffending risk and/or rehabilitation potential that can be linked to race, gender, and other social status stereotypes. This can then result in extralegal sentencing disparity connected to these statuses. Similarly, focal concerns theory describes how court actors manage uncertainty by making attributions about case and defendant characteristics in terms of four focal concerns: blameworthiness, dangerousness, rehabilitative potential, and practical constraints and consequences. In the abstract, the use of and reliance on these focal concerns are universal, but the meaning, relative emphasis and priority, and situational interpretation of them are embedded in local court community culture, organizational contexts, and politics. The important point for sentencing disparity is that while court community actors may make attributions and interpretations regarding the focal concerns primarily on the basis of legally relevant factors, they may also draw on racial, gender, class, or age stereotypes about defendants. For example, some judges may perceive young black males as particularly dangerous or lacking rehabilitative potential compared to other types of defendants, and sentence accordingly.

A third approach focuses on the organizational prioritization of expedient case processing, suggesting that heightened emphasis on the pragmatic disposition of cases places particular importance on plea bargaining. Extending Michels (1915) principle of the 'imperatives of organizational maintenance' to criminal justice organizations, Dixon notes the importance of efficient processing of cases, positing that *organizational efficiency* may be an overriding priority in sentencing decisions. In other words, Dixon (1995) defines this perspective as situating "efficient case disposition as the operational goal that maintains a stable and orderly sentencing system" (p. 1162). Drawing on this work, Engen and Steen (2000) delineate an organizational efficiency model, stressing that the importance of organizational efficiency may supersede formal rules like laws or sentencing guidelines, or substantively rational concerns like perceived blameworthiness and dangerousness. Prosecutors and judges achieve efficient case processing by encouraging guilty pleas and avoiding trials (Engen and Steen, 2000: p. 1363):

> The goal of criminal justice processing, according to this perspective, is to induce guilty pleas as an organizationally efficient means to an end. Thus offenders who plead guilty are rewarded with less severe sentences than they could otherwise have received.

Although different aspects of the sentencing process are their particular focus, each of the three approaches may lead to similar or consistent predictions regarding sentencing outcomes. For example, the organizational efficiency perspective predicts that a fundamental source of sentencing disparity will be differences across mode of conviction. Specifically, defendants who plead guilty will be sentenced more leniently than comparable individuals convicted via trial (even when controlling for differences in crime severity and prior criminal histories). Neither focal concerns nor court community perspectives refute this idea. Rather, proponents of focal concerns theory would agree with the potential for disparity based on mode of conviction. By conceptualizing pressures for organizational efficiency as one facet of the focal concern of practical constraints and consequences, focal concern proponents agree that concerns regarding the timely and efficient disposition of cases may result in sentencing disparity between those who plead guilty and those who are convicted by trial. Similarly, throughout much of the research applying the court community and organizational context frameworks, the need to process cases in a timely manner, the desire to avoid court backlogs, and the collective practice of rewarding guilty pleas and/or penalizing trials are significant themes. Notably, the court community and organizational context perspectives emphasize *variation* between local courts in the perceived importance of efficiency as a practical constraint and consequence.

Empirical Research on Sentencing: Racial/Ethnic Disparities

In the 1983 National Academy of Science assessment of sentencing research by Blumstein et al. (1983), Hagan and Bumiller review 51 studies on race and sentencing. They detail the many definitional and methodological challenges that prevent scholars from reaching collective conclusions, including weaknesses in defining and distinguishing between legal and extralegal variables, differences in sentence-severity rankings, problems with sample selection, and variation in measurement techniques. Overall, the authors found that contemporary studies were increasingly including legally relevant influences of offense severity and prior record in their designs. These variables and other processual measures, such as bail status, defense counsel, and plea, appeared to explain much of the influence of race and socioeconomic status on sentencing outcomes. Hagan and Bumiller were careful to note that these studies did not produce fewer findings of racial discrimination; rather, they identified many structural contexts where discrimination exists. However, the strength of the reported relationships between race and sentencing often seemed weak since these variables were at opposite ends of the causal chain. The processual approach to the sentencing issue is important because it highlights ways in which mediating variables like employment and bail status can be incorporated in a disadvantaging way into the sentencing process.

Reports estimate that, in 2009, African-American males were over six times more likely to be incarcerated than white males. African-American females were approximately three times more likely to be imprisoned than white females (Guerino et al., 2012). Thus, despite trends that indicate the *magnitude* of racial differences in incarceration risk is decreasing, minorities still continue to be disproportionately overrepresented in correctional populations. While many factors may affect sentencing disparities, explanations of racial and ethnic differences are key areas of public and scholarly debate. Some have argued that more severe sentences imposed on minorities are artifacts of differences in offending patterns and histories across groups. That is, they argue that the tougher

sentences imposed on minority defendants are a consequence of the higher severity of their crimes and prior criminal histories, as well as other legally relevant factors courts draw upon to determine appropriate sentences. However, critics contend that racial/ethnic discrimination in the justice process perpetuates a system in which minority defendants are punished more harshly than white defendants who have committed similar offenses and have comparable criminal histories.

Two later comprehensive reviews (Spohn, 2000; Zatz, 2000) summarized research on sentencing up to 2000, primarily focusing on studies of disparity based on defendant social characteristics. Much of this research did provide evidence of racial/ethnic differences in punishment. For example, in her review of 32 studies using state-level data, Spohn (2000) found that 41 of 95 black vs white estimates (43.2%) were significant indicators of harsher sentences for black defendants. Only four estimates suggested blacks were treated more leniently. Of the 29 effects, 8 reported significantly more severe sentences for Hispanics than whites, while only two effects indicated Hispanics were treated more leniently. In addition, 15 of 22 effects in eight federal court studies showed significant black disadvantages, while 10 of 21 effects indicated Hispanic disadvantages. Similarly, Zatz (2000) concluded that the empirical literature demonstrates distinct racial disadvantages among less serious offenses and low-level felonies, where prosecutors have the greatest amount of discretion in charging and plea-bargaining decisions.

Reviews of the direct effect of race on sentence severity reveal decidedly mixed results, it appears that disparity is more apparent in the decision to sentence offenders to prison than in the length of sentence imposed (Chiricos and Crawford, 1995). Specifically, Spohn (2000) found that, out of the 117 estimates of race effects on sentence severity, 53% indicated that blacks were more likely to receive an active prison sentence, while only 31% indicated that blacks were more likely to receive a longer sentence length.

Both reports also highlighted research that not only determined whether 'race/ethnicity mattered' or 'gender mattered,' but went on to investigate when and how these offender characteristics affect sentencing. The authors reviewed studies investigating how the influences of race, ethnicity, and gender mutually conditioned one another, and were also conditioned by other, more legitimized, factors. For example, Spohn's (2000) review provided a quantitative summary of interaction effects in racial/ethnic disparity studies, including 11 studies examining whether race and/or ethnic effects were conditioned by other social statuses or characteristics, especially gender and/or age (p. 462). All 11 provided some evidence of such effects. In particular, four studies observed sentencing disadvantages for young black and/or Hispanic males, four revealed sentencing disadvantages for unemployed young black or Hispanic males, one provided evidence of disadvantages for poor minorities, and one found disadvantages for low education minorities. Steffensmeier et al. (1998) examined the combined effects of race, age and gender on the in/out decision and sentence length; they determined that young black males were punished more harshly than any other age-race-sex combination.

In addition, much of the research in the 1990s finds that race/ethnicity differences in sentencing were conditional on criminal history, offense type or severity, case-processing factors, jurisdiction characteristics, and victim characteristics. In her review, Spohn notes that eight studies found that blacks or Hispanics with more serious criminal histories were sentenced more severely. Ten studies concluded that race/ethnic differences were conditioned by type or severity of crimes. Three found that racial disadvantages were greatest in less serious crimes, and six found that racial disadvantages were pronounced in drug offenses. In addition, six studies found that race/ethnicity effects were conditioned by case-processing factors. Two studies found that blacks were sentenced more severely if they were detained prior to trial, and one study concluded that blacks represented by a public defender received harsher sentences than those retaining a private attorney. Three studies revealed that black defendants who pled guilty were sentenced more severely than comparable black defendants convicted by trial.

Also, both at the state and federal levels, studies consistently find that sentence severity varies by jurisdiction (e.g., across county or circuit courts). Furthermore, Ulmer and Kramer (1996) explicitly compared sentencing in three Pennsylvania counties. They found significant racial disparities in only two counties. In addition, Steffensmeier and Demuth (2000) revealed that disparities may vary by type of offense, and were most pronounced among drug offenses in US courts.

Finally, Spohn notes that one study found that blacks who victimized whites received more severe sentences than other victim-offender combinations. Other studies have also found that race interacts with other variables and affects sentence severity only in some types of cases (Spohn and Cederblom, 1991). Similarly, Zatz (2000) notes that patterns associated with the victim-offender racial dyad is strongest and most consistent among homicide and rape cases. However, she suggests that the significantly harsher penalties for black male offenders among other offenses (such as burglaries, which may have white victims) is emblematic of the generalized threat that black males are believed to pose. Other studies have also found that race only interacts with other variables and affects sentence severity in some types of cases (Spohn and Cederblom, 1991).

More recent reviews of the sentence literature have been provided by Mitchell (2005) and Ulmer (2012). Since 2000, the majority of research on decisions to incarcerate (in/out decisions) finds that blacks are more likely than whites to receive prison sentences (Steffensmeier and Demuth, 2000; Ulmer and Johnson, 2004). However, not all studies find this; Weidner et al. (2005) find that black offenders are neither more nor less likely than comparable white offenders to receive active prison sentences vs jail sentences or noncustodial sentences. Notably, the majority of studies do not find that statistically significant race/ethnic differences in sentence length (e.g., LaFrentz and Spohn, 2006). In fact, some studies indicate that white defendants receive longer sentences relative to black defendants (Wooldredge et al., 2005). There are some studies that do find a disadvantage for blacks in sentence length (Ulmer and Johnson, 2004; Shermer and Johnson, 2010), depending on the type of offense (Steffensmeier and Demuth, 2000).

In a meta-analysis synthesizing 71 published and unpublished studies, Mitchell (2005) found significant racial

disparities in the likelihood of incarceration; African-American defendants were more likely than white defendants to be sent to prison. With regard to the length of sentences ordered by the court, African-Americans were generally sentenced more harshly than white defendants. However, this effect was small and highly variable. Importantly, Mitchell noted, "the observed differences between whites and African-Americans were small, suggesting that discrimination in the sentencing stage is not the primary cause of the overrepresentation of African-Americans in U.S. correctional facilities" (p. 462).

A few works examining the severity of conviction offenses (or, conversely, charge reductions) generally do not find that black offenders are convicted of more serious charges than white offenders (Albonetti, 1991; Wooldredge et al., 2005; Shermer and Johnson, 2010). However, some suggest that prosecutors are more likely to charge black defendants under mandatory minimums, although it is not clear whether they significantly increase sentence severity (Engen, 2009). Others find that white defendants are more likely to receive substantial assistance departures (Hartley et al., 2007) and downward departures (Mustard, 2001) in federal courts. However, research examining the severity of conviction offenses (or, conversely, charge reductions) generally does not find that black defendants are convicted of more serious charges than whites (Albonetti, 1991; Wooldredge et al., 2005; Shermer and Johnson, 2010). Unfortunately, evidence regarding these and other important presentencing decisions, especially charge reductions, is still relatively limited.

Overall, though, research examining the effect of race/ethnicity on sentencing has yet to resolve this debate and achieve a collective social scientific consensus. Some studies have shown that minorities are sentenced more harshly than whites (Kramer and Ulmer, 1996; Spohn et al., 1981–1982; Zatz, 1984), even after crime seriousness, prior criminal record, and other legal variables are taken into account. Other studies have found either no significant racial differences (Klein et al., 1990) or that blacks are treated more leniently than whites (Gibson, 1977). Still other research has concluded that race influences sentence severity indirectly through its effect on variables such as bail status (LaFree, 1985a), type of attorney (Spohn et al., 1981–1982), or type of disposition (LaFree, 1985b; Spohn, 1992), or that race interacts with other variables and affects sentence severity only in some types of cases (Spohn and Cederblom, 1991).

Empirical Research on Sentencing: Sex/Gender Disparities

While research on gender differences tends to find that women are sentenced more leniently than men, some studies suggest that this is not always the case. Daly and Bordt's (1995) analysis of the statistical findings of research published until 1990 found that women received less severe sentences than men in approximately half of the studies examined, mixed or no effects in 25% of the studies, and harsher sentences in 25% of the studies. In their review, Daly and Bordt (1995) found that women were more likely to receive harsher sentences if charged with felony offenses, if the cases were tried in felony courts, and if the sentencing occurred in urban areas.

Many recent studies find that men are more likely than women to receive a prison sentence vs nonprison sentence (Mustard, 2001; Spohn and Holleran, 2000; Steffensmeier et al., 1998; Weidner et al., 2005; Wooldredge et al., 2005). Studies also find that men are more likely to receive longer terms of incarceration (LaFrentz and Spohn, 2006; Shermer and Johnson, 2010). However, some works fail to find significant gender effects on sentence length (Wooldredge et al., 2005) or the likelihood of incarceration (Curry et al., 2004). In addition, while Albonetti (2002) finds that women drug offenders tend to receive more lenient sentences in comparison to their male counterparts overall, they are disproportionately disadvantaged by increases in offense level.

Much of the scholarly discussion surrounding gender and sentencing centers on how gender conditions leniency. That is, authors explore the conditional effects of gender and other demographic variables. Zatz (2000) is careful to note that the relationship between leniency and gender is not universal-highlighting studies that attempt to distinguish among which women and under what conditions this association exists. She discusses the work of Kruttschnitt (1984), arguing that gender-based family roles may make women more economically dependent on male partners and other family members. Thus formal sanctions may be deemed less necessary to control women's behavior, as they are more subject to informal social controls. In addition, she details the familial-based paternalism explanation provided by Daly (1989), which advocates greater leniency to mothers than nonmothers in the interest of avoiding the pragmatic challenges of incarcerating women with children. Bickle and Peterson (1991) found that the effect of family variables was conditional on race. Specifically, for black mothers, simply having children was not sufficient. Rather, black women must have demonstrated that they were 'good mothers' in order to receive leniency from the court. Similarly, Spohn's (2000) review provided a quantitative summary of interaction effects, including studies examining whether race and/or ethnic effects were conditioned by other social statuses or characteristics, especially gender and/or age (p. 462). All interaction studies provided some evidence of such effects. In particular, four studies found sentencing disadvantages for young males who were black and/or Hispanic males, and four revealed sentencing disadvantages for unemployed young black or Hispanic males.

Authors also explore the conditional effects of gender and process-related variables or on explaining how decision-making may disproportionately disadvantage men/advantage women throughout stages of the justice system. Studies find that women receive leniency at different sentencing stages. Men are less likely to be receive diversion options vs prosecution in drug cases (Alozie and Johnston, 2000), and are less likely to have their charges dismissed (Kingsnorth et al., 2002; Miethe, 1987) or reduced (Miethe, 1987; Mustard, 2001; Shermer and Johnson, 2010).

Empirical Research on Sentencing: Disparities across Mode of Conviction

Critics (e.g., Smith, 1986) have argued that 'plea bargains' are somewhat of a myth, in that pleading guilty may not result in

actual 'bargains' for defendants. Indeed, some offenders who plead guilty would have been acquitted or convicted of lesser offenses had they exercised their right to trial. In addition, some studies failed to find evidence that sentences significantly differed across mode of conviction (Eisenstein and Jacob, 1977). However, the bulk of evidence since the 1980s indicates that, among persons who are convicted, whether defendants pled guilty or were found guilty by trial has a unique and significant influence on their sentence (Blumstein et al., 1983; Ulmer and Bradley, 2006; Kramer and Ulmer, 2009). Moreover, although the size of the plea/trial disparity may vary, the mode of conviction (usually defined as simply whether the defendant pleaded guilty or was convicted at trial) is frequently among the strongest predictors of sentence severity, in some instances rivaling the effects of 'legally relevant' variables such as offense severity, weapon use, or prior convictions and generally having a greater impact than offender status characteristics such as gender, race/ethnicity, or age (Albonetti, 1991, 1998; Ulmer et al., 2010; Ulmer and Johnson, 2004; Miethe and Moore, 1985).

Many studies on other aspects of sentencing include controls for mode of conviction in their models. Although not the focus, by controlling for mode of conviction, these studies imply that whether a defendant has pled guilty or been convicted by trial may have a unique and significant influence on his/her sentence. In much of these works, there appears to be a 'trial penalty,' in that trial-convicted defendants are sentenced more severely than guilty-pled defendants (for some examples, see Albonetti, 1991; Dixon, 1995; Spohn et al., 1981–1982; Steffensmeier et al., 1998; Steffensmeier and Demuth, 2000; Steffensmeier and Hebert, 1999; Steffensmeier et al., 1993; Ulmer and Kramer, 1996) Most, although not all, of the studies that do focus on the effects of different modes of conviction conclude that those found guilty by trial, particularly jury trials, receive more severe sentences than similarly situated defendants who plead guilty (for example, Brereton and Casper, 1982; Johnson, 2003; Ulmer, 1997; Ulmer and Bradley, 2006). For example, in an examination of sentencing guidelines across several states, King et al. (2005) found significant 'process discounts' for some offenders. Reductions in sentence were linked to defendant conduct beyond the offense, including pleading guilty and providing assistance to law enforcement.

Moreover, offender and case characteristics may moderate the size of the trial penalty. Early research by Rhodes (1979) finds that the size of plea-trial sentencing differences varies by type of offense. He found sentencing differences across mode of conviction in robbery convictions, but not among convictions for other thefts and assault. Later studies provide further support for the notion that losing at trial can be particularly deleterious for some kinds of offenders, including African-American defendants and defendants with more extensive criminal histories (for example, Smith, 1986; Ulmer, 1997). Relatedly, Johnson (2003), in a comparison of bench vs jury convictions, found that mode of conviction conditioned the impact of race on disparities. Specifically, African-Americans were least likely to obtain downward guideline departures following trials, especially jury trials.

In addition to other factors, assessments of defendants' culpability and moral character affect determinations of appropriate punishment as judges evaluate their potential for reoffending (see also Albonetti, 1991). Thus, findings with regard to mode of conviction are often framed in terms of exposure to negative information. Recently, Ulmer and Bradley (2006) apply these concepts to examine variation in the size of the trial penalty for serious violent offenders. They suggest that pleading guilty helps defendants avoid disclosing negative information, or 'bad facts' (see Ulmer and Bradley, 2006; Brereton and Casper, 1982; Flemming et al., 1992; Ulmer, 1997). Specifically, trials provide occasions for the disclosure of information, wherein court actors hear information that adversely impacts assessment of a defendant's character. During the course of trials, prosecutors 'dirty up' defendants – they provide judges with vivid descriptions of crimes, emotional victim testimony, and detailed information regarding the defendant's past wrongs and misbehavior (Ulmer and Bradley, 2006). This information, coupled with the increased publicity and attendant public scrutiny associated with trials, may discourage judicial leniency (Brereton and Casper, 1982).

Most researchers agree that the institutionalized practice of 'rewarding' those who plead guilty and 'penalizing' those who lose at trial serves a variety of administrative or organizational needs including, but not limited to, the need for efficiency in case processing (Dixon, 1995; Engen and Steen, 2000). Other have also stressed that the plea process provides a means by which courtroom workgroups are able to pursue substantive justice; fair punishments that take into account the unique circumstances of each case, such as the defendant's culpability or danger to the community (Ulmer and Bradley, 2006), and that can even mitigate the effects of harsh sentencing laws (Mather, 1979).

Consistent with this administrative or bureaucratic justice interpretation, Dixon (1995) found that the size of the plea-trial disparity was conditional on the level of court bureaucratization. Later examinations of federal sentencing found that district-level caseload pressure significantly increases the size of trial effects on both the likelihood of sentence departures (Johnson et al., 2008) and sentence severity (Ulmer et al., 2010). Other studies have provided support for this idea, finding that trial penalties among serious violent offenders tended to be larger in counties with larger caseloads (Ulmer and Bradley, 2006) and lower trial rates (Kramer and Ulmer, 2009).

Limitations

It has long been recognized that sentencing is conditioned by selection processes in earlier justice system decisions. Several chapters of the Blumstein et al. (1983) report, as well as others called for consideration of sentencing in the contexts of earlier criminal justice decisions, particularly pretrial detention, charging, and conviction. The years since the Blumstein et al. (1983) report have seen comparatively few studies that examine sentencing in the context of earlier decisions. Consequently, evidence regarding the roles of race and gender in association with presentencing decisions, especially charge reductions, is still relatively limited. One explanation for this relative dearth is the lack of available data.

A critical development instrumental to the proliferation of sentencing research was the advent of accessibility of collected by sentencing commissions in sentencing guideline states and the federal system during the late 1980 and 1990s. These data were disseminated by sentencing commissions. Sentencing commissions operate under legal mandates, which require that they collect and make such data available. As a result, researchers had access to high-quality postconviction, jurisdiction-wide data for substantial numbers of cases. These data facilitated progress by providing substantially improved measures of offense severity and criminal history, which had often been measured crudely in earlier research, including multiple sentencing-related outcomes, and very large samples drawn from large numbers of contextually diverse counties (for states) or district courts (with federal data).

Unfortunately, guideline sentencing data are limited to convicted offenders, and do not include preconviction information such as the type and number of original charges (and rarely include pretrial detention). Data sets that include preconviction data for large numbers of cases and multiple local jurisdictions have traditionally been difficult to obtain. Relatedly, the Blumstein et al. (1983) report called for sentencing research to examine the effects of defendant socioeconomic status variables on sentencing outcomes, and to disentangle the potential influence of race and ethnicity vs socioeconomic factors in sentencing. Defendant socioeconomic data and/or data on individual court actors has generally been hard to come by in the most widely used guideline data sets. Thus, studies that disentangle socioeconomic factors from other defendant characteristics (especially race or ethnicity) have not been as common.

Furthermore, we know relatively little about sentencing variation between criminal justice actors, especially judges and prosecutors, and the effects of decision maker characteristics in explaining variation in sentencing. Only a handful of studies have examined sentencing variation between judges, and the effect of judge characteristics, and even fewer studies have examined between-prosecutor variation.

Finally, the large majority of criminological literature on sentencing focuses on courts in the United States. We generally know very little about sentencing in other countries, especially non-Western ones. Thus, increased attention to sentencing in international contexts is a major need for criminology.

Sequential Statistical Methods

Abstract

When using a sequential design the data that accrue can affect the future course of the experiment. For example, observations made early in an experiment can determine treatment assignment later in the experiment. The other principal example is when the accumulating results are used to determine when to stop the experiment. This article presents some of the methodology associated with both types of sequential experiment. Of particular importance in the sequential setting is whether one's statistical perspective is frequentist or Bayesian. This article describes the role of statistical philosophy in sequential experimentation, as well as its impact on scientific inference and decision making.

Statistics plays two fundamental roles in empirical research. One is in determining the data collection process: the experimental design. The other is in analyzing the data once it has been collected. For the purposes of this article, two types of experimental designs are distinguished: *sequential* and *nonsequential*. In a sequential design the data that accrue in an experiment can affect the future course of the experiment. For example, an observation made on one experimental unit treated in a particular way, may determine the treatment used for the next experimental unit. The term 'adaptive' is commonly used as an alternative to sequential. In a nonsequential design the investigator can carry out the entire experiment without knowing any of the interim results.

The distinction between sequential and nonsequential is murky. An investigator's ability to carry out an experiment exactly as planned is uncertain, as information that becomes available from within and outside the experiment may lead the investigator to amend the design. In addition, a nonsequential experiment may give results that encourage the investigator to run a second experiment, one that might even simply be a continuation of the first. Considered separately, both experiments are nonsequential, but the larger experiment that consists of the two separate experiments is sequential.

In a typical type of nonsequential design, 20 patients suffering from depression are administered a drug and their improvements are assessed. An example sequential variation is the following. Patients' improvements are recorded 'in sequence' during the experiment. The experiment stops should it happen that at least nine of the first 10 patients, or no more than one of the first 10 patients improve(s). On the other hand, if between two and eight of the first 10 patients improve then sampling continues to a second set of 10 patients, making the total sample size equal to 20 in that case. Another type of sequential variation is when the dose of the drug is increased for the second 10 patients should it happen that fewer than four of the first 10 improve.

Much more complicated sequential designs are possible. For example, the first patient may be assigned a dose in the middle of a range of possible doses. If the patient improves then the next patient is assigned the next lower dose, and if the first patient does not improve then the next patient is assigned the next higher dose. This process continues, always dropping the dosage if the immediately preceding patient improved, and increasing the dosage if the immediately preceding patient did not improve. This is called an 'up-and-down' design.

Procedures in which batches of experimental units (such as groups of 10 patients each) are analyzed before proceeding to the next stage of the experiment are called 'group-sequential.' Designs such as the up-and-down design, in which the course of the experiment can change after each experimental unit responds are called 'fully sequential.' So a fully sequential design is a group-sequential design in which the group size is one. Designs in which the decision of when to stop the experiment depends on the accumulating results are called 'sequential stopping.' Using rules to determine which treatments to assign to the next experimental unit or batch of units is called 'sequential allocation.'

Designs of most scientific experiments are sequential, although perhaps not formally so. Investigators usually want to conserve time and resources. In particular, they do not want to continue an experiment if they have already learned what they set out to learn, and this is so whether their conclusion is positive or negative, or if finding a conclusive answer would be prohibitively expensive. (Where the investigator discovers that the standard deviation of the observations is much larger than originally thought is an example of an experimental design that would be prohibitively expensive to continue because the required sample size would be large.)

Sequential designs are difficult or impossible to use in some investigations. For example, results might take a long time to obtain, and waiting for them would mean delaying other aspects of the experiment. Suppose one is interested in whether grade-schoolers diagnosed with attention deficit hyperactivity disorder (ADHD) should be prescribed Ritalin. The outcome of interest is whether children on Ritalin will be addicted to drugs as adults. Consider assigning groups of 10 children to Ritalin and 10 to a placebo, and waiting to observe their outcomes before deciding whether to assign an additional group of 10 patients to each treatment. The delay in observation means that it would probably take hundreds of years to get an answer to the overall question. The long-term nature of the endpoint means that any reasonable experiment addressing this question would necessarily be non-sequential, with large numbers of children assigned to the two groups before any information at all would become available about the endpoint.

Analyzing Data from Sequential Experiments – Frequentist Case

Consider an experiment of a particular type, say one to assess extrasensory perception (ESP) ability. A subject claiming to have ESP is asked to choose between two colors. The *null hypothesis* of no ability is that the subject is only guessing, in which case the correct color has a probability of 1/2. Suppose the subject gets 13 correct out of 17 tries. How should these results be analyzed and reported? The answer depends on one's statistical philosophy. Frequentists and Bayesians take different approaches. Frequentist analyses depend on whether the experiment's design is sequential, and if it is sequential the conclusions will differ depending on the actual design used.

In the nonsequential case the subject is given exactly 17 tries. The frequentist *P*-value is the probability of results as extreme as or more extreme than those observed. The results are said to be 'statistically significant' if the *P*-value is less than 5%. A convention is to include both 13 or more successes and 13 or more failures. (This 'two-sided' case allows for the possibility that the subject has ESP but has inverted the 'extrasensory' signals.) Assuming the null hypothesis and that the tries are independent, the probabilities of the number of successes is binomial. Binomial probabilities can be approximated using the normal distribution. The z-score for 13 out of 17 is about 2, and so the probability of 13 or more successes or 13 or more failures is about 0.05 (the exact binomial probability is 0.049), and so the results are statistically significant at the 5% level and the null hypothesis is rejected.

Now suppose the experiment is sequential. The frequentist significance level is now different, and it depends on the actual design used. Suppose the design is to sample until the subject gets at least four successes and at least four failures – same data, different design. Again, more extreme means more than 13 successes (and exactly four failures) or more than 13 failures (and exactly four successes). The total probability of these extreme values is 0.021 – less than 0.049 – and so the results are now more highly significant than if the experiment's design had been nonsequential.

Consider another sequential design, one of a type of group-sequential designs commonly used in clinical trials. The experimental plan is to stop at 17 tries if 13 or more are successes or 13 or more are failures, and hence the experiment is stopped on target. But if after 17 tries the number of successes is between five and 12, then the experiment continues to a total of 44 tries. If at that time, 29 or more are successes or 29 or more are failures then the null hypothesis is rejected. To set the context, suppose the experiment is nonsequential, with sample size fixed at 44 and no possibility of stopping at 17; then the exact significance level is again 0.049. When using a sequential design, one must consider all possible ways of rejecting the null hypothesis in calculating a significance level. In the group-sequential design, there are more ways to reject than in the nonsequential design with the sample size fixed at 17 (or fixed at 44). The overall probability of rejecting is greater than 0.049 but is somewhat less than $0.049 + 0.049$ because some sample paths that reject the null hypothesis at sample size 17 also reject it at sample size 44. The total probability of rejecting the null hypothesis for this design is actually 0.080. Therefore, even though the results beyond the first 17 observations are never observed, the fact that they might have been observed makes 13 successes of 17 no longer statistically significant (since 0.08 is greater than 0.05). The three designs above are summarized in Table 1. The table includes a fourth design in which the significance level cannot be found.

To preserve a 0.05 significance level in group-sequential or fully sequential designs, investigators must adopt more stringent requirements for stopping and rejecting the null hypothesis; that is, they must include fewer observations in the region where the null hypothesis is rejected. For example, the investigator in the above study might drop 13 successes or failures in 17 tries and 29 successes or failures in 44 tries from the rejection region. The investigator would stop and claim significance only if there are at least 14 successes or at least 14 failures in the first 17 tries, and claim significance after 44 tries only if there are at least 30 successes or at least 30 failures. The *nominal significance levels* (those appropriate had the experiment been nonsequential) at $n = 17$ and $n = 44$ are 0.013 and 0.027, and the overall (or adjusted) significance level of rejecting the null hypothesis is 0.032. (No symmetric rejection regions containing more observations allow the significance level to be greater than this but still smaller than 0.05.) With this design, 13 successes out of 17 is not statistically significant (as indicated above) because this data point is not in the rejection region. The above discussion is in the context of significance testing. But the same issues apply in all types of frequentist inferences, including confidence intervals.

The implications of the need to modify rejection regions depending on the design of an experiment are profound. In view of the penalties that an investigator pays in significance level that are due to repeated analyses of accumulating data, investigators strive to minimize the number of such analyses. They shy away from using sequential designs and so may miss opportunities to stop or otherwise modify the experiment depending on accumulating results.

What happens if investigators fail to reveal that other analyses did occur, or that the experiment might have continued had other results been observed? Any frequentist conclusion that fails to take the other analyses into account is meaningless. Strictly speaking, this is a breach of scientific ethics when carrying out frequentist analyses. But it is difficult to find fault with investigators who do not understand the subtleties of frequentist reasoning and who fail to make necessary adjustments to their inferences.

For more information about the frequentist approach to sequential experimentation, see Whitehead (1992).

Table 1 Summary of experimental designs and related significance levels

Stopping rule	*Significance level*
After 17 observations (nonsequential)	0.049
After at least 4 successes and 4 failures	0.021
After 17 or 44 observations, depending on interim results	0.08
Stop when 'you think you know the answer'	Undefined

Analyzing Data from Sequential Experiments – Bayesian Case

When taking a Bayesian approach (*see* Bayesian Statistics) (or a likelihood approach), conclusions are based only on the observed experimental results and do not depend on the experiment's design. So the murky distinction that exists between sequential and nonsequential designs is irrelevant in a Bayesian approach. In the example considered above, 13 successes out of 17 tries will give rise to the same inference in each of the designs considered. Bayesian conclusions depend only on the data actually observed and not otherwise on the experimental design (Berger and Wolpert, 1984; Berry, 1987).

The Bayesian paradigm is inherently sequential. Bayes' theorem prescribes the way learning takes place under uncertainty. It specifies how an observation modifies one's state of knowledge (Berry, 1996). Moreover, each observation that is planned has a probability distribution. After 13 successes in 17 tries, the probability of success on the next try can be found. This requires a distribution, called a 'prior distribution,' for the probability of success on the first of the 17 tries. Suppose the prior distribution is uniform from 0 to 1. (This is symmetric about the null hypothesis of 1/2, but it is unlikely to be anyone's actual prior distribution in the case of ESP because it gives essentially all the probability to *some* ESP ability.) The predictive probability of a success on the 18th try is then $(13+1)/(17+2) = 0.737$, called 'Laplace's rule of succession' (Berry, 1996: p. 204). Whether to take this 18th observation can be evaluated by weighing the additional knowledge gained (having 14 successes out of 18, with probability 0.737, or 13 successes out of 18, with probability 0.263) with the costs associated with the observation.

Predictive probabilities are fundamental in a Bayesian approach to sequential experimentation. They indicate how likely it is that the various possibilities for future data will happen, given the data currently available. Suppose that after 13 successes of 17 tries one is entertaining taking an additional 27 observations. One may be interested in getting at least 30 successes out of the total of 44 observations – which means at least 17 of the additional 27 observations are successes. The predictive probability of this is about 50%. Or one may be interested in getting successes in at least 1/2 (22) of the 44 tries. The corresponding predictive probability is 99.5%.

The ability to use Bayes' theorem for updating one's state of knowledge and the use of predictive probabilities makes the Bayesian approach appealing to researchers in the sequential design of experiments. As a consequence, many researchers who prefer a frequentist perspective use the Bayesian approach in the context of sequential experimentation. If they are interested in finding the frequentist operating characteristics (such as significance level and power), these can be calculated by simulation.

The next section (Section Sequential Allocation of Experiments: Bandit Problems) considers a special type of sequential experiment. The goals of the section are to describe some of the calculational issues that arise in solving sequential problems and to convey some of the interesting aspects of sequential problems. It takes a Bayesian perspective.

Sequential Allocation of Experiments: Bandit Problems

In many types of experiments, including many clinical trials, experimental units are randomized in a balanced fashion to the candidate treatments. The advantage of a balanced design is that it gives maximal information about the differences between treatments. In some types of experiment, including some clinical trials, it may be important to obtain good results on the units that are part of the experiment. Treatments – or *arms* – are assigned based on accumulating results; that is, assignment is sequential. The goal is to maximize the overall effectiveness – of those units in the experiment, but also, perhaps, including those units not actually in the experiment but whose treatment might benefit from information gained in the experiment.

Specifying a design is difficult. The first matter to be considered is the arm selected for the initial unit. Suppose that the first observation is X_1. The second component of the design is the arm selected next, given X_1 and also given the first arm selected. The third component depends on X_1 and the second observation X_2, and on the corresponding arms selected. And so on. A design is *optimal* if it maximizes the expected number of successes. An arm is optimal if it is the first selection of an optimal design.

Consider temporarily an experiment with n units and two available arms. Outcomes are dichotomous: arm 1 has success probability p_1 and arm 2 has success probability p_2. The goal is to maximize the expected number of successes among the n units. Arm 1 is standard and has known success proportion p_1. Arm 2 has unknown efficacy. Uncertainty about p_2 is given in terms of a prior probability distribution. To be specific, suppose that this is uniform on the interval from 0 to 1.

If $n = 1$ then the design requires only an initial selection, arm 1 or arm 2. Choosing arm 1 has expected number of successes p_1. Choosing arm 2 has conditional expected number of successes p_2, and an unconditional expected number of successes, the prior probability of success, which is 1/2. Therefore arm 1 is optimal if $p_1 \geq 1/2$ and arm 2 is optimal if $p_1 \leq 1/2$. (Both arms – and any randomization between them – are optimal when $p_1 = 1/2$.)

The problem is more complicated for $n \geq 2$. Consider $n = 2$. There are two initial choices and two choices depending on the result of the first observation. There are eight possible designs. One can write a design as $\{a;\ a_s,\ a_F\}$, where a is the initial selection, a_s is the next selection should the first observation be

Table 2 Possible designs and associated expected number of successes

Design	*Expected number of successes*
{1; 1, 1}	$\mathbf{2p_1}$
{1; 1, 2}	$p_1 + p_1^2 + (1-p_1)/2$
{1; 2, 1}	$p_1 + p_1/2 + (1-p_1)p_1$
{1; 2, 2}	$p_1 + 1/2$
{2; 1, 1}	$1/2 + p_1$
{2; 1, 2}	$1/2 + (1/2)p_1 + (1/2)(1/3)$
{2; 2, 1}	$\mathbf{1/2 + (1/2)(2/3) + (1/2)p_1}$
{2; 2, 2}	$\mathbf{2(1/2) = 1}$

Table 3 The optimal expected proportion of successes for selected values of n and for fixed $p_1 = 1/2$

n	1	2	5	10	20	50	100	200	500	1000	10 000
Proportion of successes	0.500	0.542	0.570	0.582	0.596	0.607	0.613	0.617	0.621	0.622	0.624

Table 4 The breakeven values of p_1^* for selected values of n

n	1	2	5	10	20	50	100	200	500	1000	10 000
p_1^*	0.500	0.556	0.636	0.698	0.758	0.826	0.869	0.902	0.935	0.954	0.985

a success, and a_F is the next selection should the first observation be a failure. To find the expected number of successes for a particular design, one needs to know such quantities as the probability of a success on arm 2 after a success on arm 2 (which is 2/3) and the probability of a success on arm 2 after a failure on arm 2 (which is 1/3). The possible designs and their associated expected numbers of successes are given in Table 2.

It is easy to check that only three of these expected numbers of successes (shown in bold) are candidates for the maximum. If $p_1 \geq 5/9$ then $\{1; 1, 1\}$ is optimal; if $1/3 \leq p_1 \leq 5/9$ then $\{2; 2, 1\}$ is optimal; and if $p_1 \leq 1/3$ then $\{2; 2, 2\}$ is optimal. For example, if $p_1 = 1/2$ then it is optimal to use the unknown arm 2 initially. If the outcome is a success, then a decision is made to 'stay with a winner' and use arm 2 again. If a failure occurs, then the decision is made to switch to the known arm 1.

Enumeration of designs is tedious for large n. Most designs can be dropped from consideration based on theoretical results (Berry and Fristedt, 1985). For example, there is a breakeven value of p_1, say p_1^*, such that arm 1 is optimal for $p_1 \geq p_1^*$. Also, one need consider only those designs that continue to use arm 1 once it has been selected. But many designs remain. Backward induction can be used to find an optimal design (Berry and Fristedt, 1985).

Table 3 gives the optimal expected proportion of successes for selected values of n and for fixed $p_1 = 1/2$. Asymptotically, for large n, the maximal expected proportion of successes is 5/8, which is the expected value of the maximum of p_1 and p_2. Both arms offer the same chance of success on the current unit, but only arm 2 gives information that can help in choosing between the arms for treating later units.

Table 4 gives the break-even values of p_1^* for selected values of n. This table shows that information is more important for larger n. For example, if $p_1 = 0.75$ then arm 1 would be optimal for $n = 10$, but it would be advisable to test arm 2 when $n = 100$; this is so even though arm 1 has probability of 0.75 of being better than arm 2.

When there are several arms with unknown characteristics, the problem is still more complicated. Optimal designs may well indicate selection of an arm that was used previously and set aside in favor of another arm because of inadequate performance. For the methods and theory for solving such problems, see Berry (1972), and Berry and Fristedt (1985). The optimal designs are generally difficult to describe. Berry (1978) provides easy to use sequential designs that are not optimal but that perform reasonably well.

Suppose the n units in the experiment are a subset of the N units on which arms 1 and 2 can be applied. Berry and Eick (1995) consider the case of two arms with dichotomous response and show how to incorporate all N units into the design problem. They find the optimal Bayes design when p_1 and p_2 have independent uniform prior distributions. They compare this with various other sequential designs and with a particular nonsequential design: balanced randomization to arms 1 and 2. The Bayes design performs best on average, of course, but it is robust in the sense that it outperforms the other designs for essentially all pairs of p_1 and p_2.

Further Reading

The pioneers in sequential statistical methods were Wald (1947) and Barnard (1944). They put forth the sequential probability ratio test (SPRT), which is of fundamental importance in sequential stopping problems. The study of the SPRT dominated the theory and methodology of sequential experimentation for decades.

For further reading about Bayesian versus frequentist issues in sequential design, see Berger (1986), Berger and Berry (1988), Berger and Wolpert (1984), and Berry (1987, 1993). For further reading about the frequentist perspective, see Chow et al. (1971) and Whitehead (1992). For further reading about Bayesian design issues, see Berry (1993), Berry and Stangl (1996), Chernoff and Ray (1965), Cornfield (1966), and Lindley and Barnett (1965). Abstract

The ability of an organism to monitor and maintain information about the nature of the world around them is a critical life function. Over the past several decades, a substantial body of evidence has been amassed that highlights the properties, functions, and neural substrates of serial order memory in both humans and nonhuman animal subjects. This article focuses on examining what is known about the neural basis of serial order memory and its dependence upon the prefrontal cortex.

Serial order working memory, the ability to monitor the temporal occurrence of stimuli and/or events, is a function essential to higher-order cognitive processing and the planning/execution of complex actions. Furthermore, this process has been consistently shown to be dependent upon the integrity of the dorsolateral prefrontal cortex (dlPFC), via human and animal studies, such that damage or maldevelopment of this area impairs performance of serial order tasks (Petrides, 2005). The following sections will highlight the evidence from human and animal studies, which collectively, characterize the neural basis of serial order memory, and highlight what is known about the roles of the dlPFC and medial temporal lobe structures in supporting serial order memory.

Prior to the discussion of serial order memory it is important to acknowledge that this term has been used to define a wide range of cognitive functions, which are far beyond the scope of this article. This article will focus on serial order memory as it pertains to working memory, specifically: the intentional mental maintenance, monitoring, or manipulation of the temporal order of stimuli that can then be utilized for the planning and execution of subsequent actions. In many contexts, serial order can also be used to describe relative familiarity, aspects of episodic memory, and the ability to repeat motor sequences that have been learned over many trials. This article aims to describe the basis of serial order working memory by highlighting neuropsychological investigations of both human and nonhuman animal subjects.

Human Serial Order Memory

Effects of Focal Brain Lesions

Historically, one of the most powerful techniques in neuropsychology has been to quantify the behavior of interest in human subjects following focal brain lesions. The utility of patients with focal brain lesions is particularly evident when considering what has been learned from Tan (Paul Broca's patient), Phineas Gage, and Patient HM. While these case studies of single individuals are few and far between, the knowledge that has been gained from the meticulous study of these individuals has proven invaluable in its ability to inform and direct research in this field.

An early study by Petrides and Milner (1982) examined the effects of frontal and temporal brain lesions on the performance of a self-ordered pointing task (SOPT) in human subjects. The SOPT was based upon a serial response task originally designed and implemented for use in investigating the consequences of frontal cortical excisions in nonhuman primates (Pinto-Hamuy and Linck, 1965; Brody and Pribram, 1978). The SOPT directly measures serial order memory by requiring subjects to monitor their behavioral selections over a series of trials. Initially, subjects are shown an array of images, as few as six and as many as 12 individual images, and were asked to point to any single image. Following image selection a delay is imposed, after which the subject is presented again with the entire image set, albeit in a new spatial orientation. On subsequent trials, the subject is asked to select an image they had not selected on the previous trial(s), until all images have been selected across the series of trials. The object of the task was for the subject to select each image only once over the series of trials, thus requiring the subject to monitor the images they have selected as a new spatial array is presented on each trial to preclude the use of a spatial strategy. Data collected in the aforementioned investigation demonstrated that damage to the frontal cortex was sufficient to impair serial order memory, a finding that has been confirmed in two independent investigations of human subjects with focal frontal cortical brain lesions (Wiegersma et al., 1990; Kesner et al., 1994).

It should also be noted that there is evidence to suggest that the temporal lobe may play a critical role in the regulation of serial order memory. Several studies have characterized serial memory impairments in individuals with medial temporal lobe lesions (Petrides and Milner, 1982; Dennis et al., 1988; Mayes et al., 2001). However, given that the subjects in these studies consisted of patients with large temporal lobe resections due to intractable epilepsy in two cases (Petrides and Milner, 1982; Dennis et al., 1988) and a single amnesic subject (Mayes et al., 2001), caution should be used in drawing strong inferences from these data. Cumulatively, these studies support a role for the medial temporal lobe in serial order memory and simultaneously substantiate the need for further investigation into the precise role of the individual medial temporal lobe structures in serial order memory. In one such case, a study quantified memory in three clinical populations: patients with selective lesions of the frontal cortex, Korsakoff's Syndrome amnesiacs, and non-Korsakoff's amnesiacs (Shimamura et al., 1990). Congruent with previous studies,

that investigation found impaired memory for word sequencing but intact word recognition and recall in the frontal cortical lesion group. In contrast, both of the amnesiac patient groups were impaired on word sequencing, recall, and recognition. Cumulatively, these findings further support the argument that the frontal cortex is a critical mediator of serial order memory, while acknowledging that the temporal cortex is a component of the neural network supporting serial order memory. To further elucidate the role of the prefrontal cortex (PFC) in serial order memory, neuroimaging studies that employed serial order memory tasks in human subjects will be detailed.

Neuroimaging

The advent of neuroimaging techniques, including functional magnetic resonance imaging (fMRI) and positron emission tomography (PET), has enabled neuropsychologists to glean a greater understanding of the neural substrates of behavior. In the case of serial order memory, the implementation of neuroimaging approaches enabled an independent investigation of the role the dlPFC plays in supporting serial order memory. While subsequent neuroimaging studies may have been driven by a desire to substantiate the activity of the dlPFC in serial order memory, it also enabled the identification of additional contributors to the neural network supporting serial order. One of the earliest neuroimaging studies of serial order memory utilized $H_2^{15}O$ PET to measure regional cerebral blood flow while subjects performed one of two behavioral tasks: Task One required the subject to remember sequences of numbers that they had generated (self-ordered), while Task Two required the subject to remember sequences of numbers that were given by the experimenter (externally ordered) (Petrides et al., 1993). The goals of this PET study of serial order memory were two-fold: to investigate the role of the frontal cortex in serial order memory and to compare the activation of the frontal cortex, as evidenced by changes in regional cerebral blood flow, between self- and externally ordered numerical sequences. In this case, the data demonstrated that the frontal cortex, specifically the dlPFC, was significantly activated in both serial order memory conditions. Furthermore, the PET analysis also revealed no difference in the magnitude or location of dlPFC activation between the two conditions, which suggests that the dlPFC is activated when sequential information is being monitored, irrespective of the origin of the sequence. Expanding upon this finding, Stern et al. (2000) utilized abstract black and white images in their study of serial order memory to preclude subjects from employing a verbal strategy to monitor the sequence of information presented. The elimination of the verbal component to the serial order task provided for a 'purer' measure of serial order memory and which should more clearly identify brain structures selectively activated by sequence monitoring. Analysis of the fMRI data from this experiment identified, once again, a selective activation of the dlPFC related to the monitoring of the serial position of stimuli. Together, these studies support the assertion that the activation observed in the dlPFC in serial order memory is a function of the monitoring requirements of each of the three tasks, as opposed to the nature of the information to be remembered.

It is important to note that while the dlPFC has been consistently identified as a critical mediator of serial order memory, this structure does not function independently and rather is a member of an interdependent cellular network supporting this memory. Specifically, the aforementioned neuroimaging studies have detected consistent activation associated with serial order memory in the following structures: ventrolateral PFC, frontopolar cortex, premotor cortex (in verbal serial order tasks), posterior parietal cortex, and medial temporal lobe. The role that each of these structures plays in supporting serial order memory has, however, not yet been substantiated (these structures will be revisited in: 2. *Serial Order Memory: Nonhuman Animal Studies*). To further explore the neurobiological basis of serial order, an examination of the developmental literature will be highlighted in the following, specifically examining the functional emergence of serial order proficiency and concomitant maturation of the frontal cortex.

Effects of Development

In parallel to examinations of cognitive function in healthy adults, investigators have frequently examined the time course of the developmental maturation of cognitive functions from birth through early adulthood. Studies that track the sequential progression of neuropsychological development are particularly informative due to the dynamic nature of the maturing nervous system. Theoretically, cognitive functions should emerge relatively consistently across the developmental window of a species and parallel the time course of the maturation of the structure(s) that support them. Fortunately, due to the exhaustive efforts of researchers examining the developing nervous system at multiple levels and developmental time points, the delayed maturation of the PFC and the simultaneous emergence of associated cognitive functions has been extensively characterized (Goldman-Rakic, 1987; Teffer and Semendeferi, 2012). Cumulatively, the literature supports the notion that the brain, in particular the frontal cortex, continues to develop through young adulthood as a function both of experience-dependent plasticity and strong genetic influence (Giedd et al., 2010).

Studies of serial order across development have further substantiated the protracted development of the frontal cortex and its associated cognitive functions. A cross-sectional study by Crone et al. (2006) sought to examine the functional development of serial order memory in three groups of children/adolescents: 8–12, 13–17, and 18–25 years of age. In this study, the investigators compared the performance and brain activation elicited while performing two serial order memory tasks of subjects. The two tasks differed in that the first required subjects to monitor the serial presentation of representational drawings in the order that they were presented (i.e., if a truck was presented first in the series of three objects and they were asked what position the truck occupied they would answer: one). In the second task, subjects were required to mentally reverse the order of the representational drawings (i.e., if a truck was presented first in the series of three objects and they were asked what position the truck occupied they would answer: three). The mental reversal of visual stimuli requires subjects to manipulate the order of the drawings that were presented to them and as such should require greater neural resources to

complete successfully. An examination of the results of this cross-sectional developmental study identified age-related increases in performance on the serial order task and corresponding increases in activation of the dlPFC during task performance. Additionally, the data also showed that while both serial order tasks produced robust activations of the dlPFC, the task that required the subjects to mentally manipulate serial position information produced a stronger activation of the dlPFC. However, the youngest group, aged 8–12 years, failed to differentially activate the dlPFC in the manipulation versus maintenance conditions, which corresponded to a reduction in the accuracy on the manipulation trials. These data further support the notion that the postnatal development of the dlPFC is what enables age-related increases in proficiency in these types of tasks. To further explore the relationship between dlPFC activation and memory accuracy, the task from the aforementioned experiment was modified to examine the effects of increasing memory load across two age groups: 11–13 and 18–25 (Jolles et al., 2011). In this case, the original task employed by Crone et al. (2006) was modified to examine the effect of memory load by varying the number of stimuli to be remembered in the sequence from a fixed number of three stimuli, to series of three, four, and five stimuli. The primary finding of this investigation confirmed the earlier report of age-related increases in serial order memory performance, which was correlated with the magnitude of dlPFC activation. In contrast, the investigators found increased activity in the ventrolateral PFC of the younger children, perhaps as a compensatory mechanism for inadequate dlPFC functionality. However, while the accuracy of subjects decreased with increasing memory load, no significant differences in the activation pattern of the dlPFC were observed. Taken together, these data support the notion that competency in serial order memory matures over a long developmental timescale and parallels the functional capacity of the dlPFC.

As is the case in many fields, cognitive psychologists frequently examine the pathology associated with disease states to try to ascertain what is 'normal.' Thus, an examination of serial order memory in psychiatric and neurological diseases, which have stereotypical neuropathology, including the frontal and temporal cortices, may provide valuable insights into the basis of serial order.

Effects of Mental Illness

Consistently, severe disorders, especially neurodevelopmental and neurodegenerative have been documented to show comorbid cognitive impairments related to the neuropathology of the corresponding brain structures. For example, impairment in working memory is now acknowledged as a consistent biomarker in schizophrenia, likely due to the gross abnormalities and associated dysfunction of the dlPFC of affected individuals (Barch and Ceaser, 2012). Not surprisingly, studies have found impaired serial order memory in individuals with schizophrenia (Fraser et al., 2004) and their impairment on serial order discriminations parallels their impairment on other prefrontal-dependent measures, including the Wisconsin Card Sorting Task (Schwartz et al., 1991). The findings of impaired serial order memory and corresponding frontal cortical neuropathology provide additional support for the dlPFC as a critical mediator of serial order memory, although it is possible that the deficits in working memory performance may also be related to altered dopamine neurotransmission to the dlPFC (Lodge and Grace, 2006).

The assertion that a reduction in dopamine transmission to the PFC could be responsible for the observed impairment in schizophrenia is substantiated by findings showing impaired serial order memory in Parkinson's disease (Shipley et al., 2002). At the same time, it must also be acknowledged that the mechanisms for these two types of dysfunction could be entirely unrelated. Furthermore, the impairment of serial order memory in Parkinson's disease does not directly correlate with other disease-related measures, such as tremor, and likely precedes the major motor pathology (Shipley et al., 2002). Finally, it is quite possible that the etiology of the impairment may be dramatically different in neurodevelopmental and neurodegenerative diseases such as schizophrenia and Parkinson's disease, respectively.

In a third example, while Alzheimer's disease (AD) is neuropsychologically typified by impaired episodic recognition, and semantic memory, investigations into AD have highlighted additional cognitive impairments associated with the disorder. In particular, it seems that impaired serial order memory is a consistent finding across the AD spectrum, from mildly impaired to late stage AD (Johnson and Kesner, 1997). Furthermore, a recent study sought to explore the nature of the serial order deficit in AD and other types of dementia, specifically vascular dementia (Hampstead et al., 2010). The results of the comparative dementia study found that while both AD and vascular dementia patients were impaired on serial order judgments, the temporal order impairment in the vascular dementia group was significantly more pronounced. As the primary initial observed neuropathology in vascular dementia typically is localized within the frontal cortex, as compared to the prototypical temporal lobe pathology of AD, it is not surprising that the vascular dementia patient group has been found to be more impaired on serial order tasks.

Collectively, the data from psychiatric and neurological disorders with respect to serial order memory provide invaluable confirmation of the sensitivity of serial order memory with further evidence of its functional dependence upon the dlPFC. First, the severity of the temporal order memory impairment is far greater in schizophrenia and vascular dementia than in Parkinson's disease or AD and is likely due to the extent of neuropathology within the frontal cortex of both schizophrenia and vascular dementia patients. Secondly, it is likely that the impairment in serial order memory in Parkinson's disease and AD is due to damage to the ventral tegmental dopaminergic system and temporal lobe, respectively, which may account for the more moderate impairment characterized in these two disorders. Thirdly, it seems that while the monitoring of serial information is a functional property of the dlPFC, it is clear that other regions, including the temporal lobe, mesolimbic dopamine system, and the posterior parietal cortex, are critical members of the neural circuit supporting serial order memory. For further insight into the neuropsychological substrates of serial order memory, an examination of the experimental animal literature is necessary.

Serial Order Memory in Nonhuman Animals

As has been the case with most neuropsychological areas of study, investigators frequently turn to a comparative animal model system to supplement the direct study of neuropsychology in human subjects, for a variety of reasons. While it is true that studies of patients with focal brain lesions can prove invaluable in enhancing our understanding of brain structure–function relationships, as evidenced by Patient HM, the relative paucity of such individuals necessitates alternative approaches. As such, the fundamental advantage to employing nonhuman models of neuropsychological function lies in the ability of the investigator to examine the direct consequence of selective brain lesions and its impact on cognitive function(s).

Nonhuman Primates

The use of nonhuman primate models of higher cognitive function has proved an invaluable resource for investigators who are interested in the neural basis of behavior. Nonhuman primates are an advantageous model system due to the degree of homology in neural architecture, protracted cognitive/physical development, and the ability to assay cognitive functions in a manner similar, or in some cases identical, to the way it is assessed in human subjects (Passingham, 2009). Studies of serial order memory in nonhuman primates date back as far as the early twentieth century to those on the effects of focal brain lesions in the chimpanzee (*Pan troglodytes*) (Jacobsen et al., 1935). The initial study by Jacobsen sought to examine the consequence of frontal lobe ablation on the performance of a sequence of responses to retrieve a food reward. In two separate paradigms it was demonstrated that the bilateral, but not unilateral, frontal lesions were sufficient to impair the performance of a sequence task that involved the monitoring of task progression to determine the direction or location of subsequent responses. In other words, bilateral frontal lesions impaired performance when the subject was required to track the serial progress of their own responses to determine the appropriate action that will lead to reward. A subsequent study, conducted in the same laboratory, examined the consequence of both lateral prefrontal cortical and inferotemporal lesions in the rhesus macaque (*Macaca mulatta*) on a serial response task. The results of this experiment demonstrated that frontal but not inferotemporal lesions were sufficient to impair an internally guided sequential task, confirming the earlier finding of Jacobsen in the chimpanzee (Pinto-Hamuy and Linck, 1965).

Years later, a resurgence in the focus of studies of serial order in humans sparked renewed interest in examining the basis of serial order memory in nonhuman primates. A preliminary study by Gower (1992) demonstrated that serial order memory in the macaque monkey is comparable to humans, both in terms of primacy/recency effects and the delay/temporal distance-based decrement in performance. Furthermore, a series of studies sought to definitively identify the locus of serial order memory tested rhesus macaques with focal lesions of the dlPFC on both self- and externally ordered serial order memory tasks (Petrides, 1991a,b, 1995). Collectively, this series of studies demonstrated that the dlPFC is a critical mediator of serial order memory, such that lesions of the dlPFC, but not other frontal cortical areas, selectively impair performance on self- and externally ordered serial tasks. The data collected in these experiments, which examined the performance of macaque monkeys on multiple independent serial order tasks, are particularly compelling in that they clearly demonstrated that the monitoring of information was the critical factor supported by the dlPFC, regardless of the nature of the information to be monitored. A pair of single-unit electrophysiological studies in the macaque monkey provided further support, for the role of the dlPFC, in supporting serial order memory. Cumulatively, the electrophysiological studies of self-ordered serial memory tasks reported selective task- and load-dependent increases in neuronal firing within the dlPFC, further substantiating the findings of the earlier lesion studies (Ninokura et al., 2003; Hasegawa et al., 2004).

The initial and still only study by Kimble and Pribram (1963) demonstrated that large hippocampal lesions were sufficient to impair performance on a serial response task, a finding that was later replicated in human subjects (Petrides and Milner, 1982). However, due to the large size of the lesions it is not possible to say whether the observed impairment in serial order working memory was due to damage of the hippocampus, adjacent cortical areas in the medial temporal lobe, or a combination of the two. To date, no study has measured the effects of selective hippocampal lesions on the performance of serial order memory tasks in adult nonhuman primates. Two recent studies have shown that neonatal lesions of the hippocampus are sufficient to impair the performance of both self- and externally guided serial order memory tasks (Heuer and Bachevalier, 2011, 2013). However, because the hippocampal lesions were performed in neonates the interpretation of these findings is inherently complicated. The observed impairment in serial order memory could have resulted from lack of a functional hippocampus in adulthood, a disruption of the normal development of the dlPFC due to hippocampal damage, or a combination of these two possibilities. The complexity of interpreting the results of neonatal hippocampal lesions is further substantiated by the neonatal hippocampal lesion model of schizophrenia, in rats, which demonstrates that early hippocampus damage results in impaired medial prefrontal cortical function in adulthood (Lipska, 2004). Given the relative paucity of data in primates as to the impact of hippocampal lesions on serial order memory, the focus of this article will now shift to rodent models of cognition.

Rodents

In parallel to nonhuman primate studies of serial order memory, extensive research has also been conducted in rodent species, specifically rats (*Rattus norvegicus*). Before discussing the results of the rodent data, there are some differences in the cognitive assessment, memory capacity, and neuroanatomy of the rat as it pertains to the administration and interpretation of serial order tasks that should be addressed. In particular, it is important to note the differences in studies of serial order memory in rats as compared to those of human and nonhuman primates. First, as rodents have well-developed spatial and olfactory abilities, the serial order tasks in

rodents typically employ a radial-arm maze, olfactory stimuli, or combinations of the two. Secondly, while both humans and nonhuman primate subjects can monitor and discriminate between adjacent items in lists of five stimuli, the literature suggests that the rats' ability to discriminate adjacent stimuli in a sequential list is limited, at best. The inherent limitation of the rat to discriminate between adjacent stimuli may suggest that it is utilizing a strategy other than the monitoring of stimuli (e.g., relative familiarity or recency). Thirdly, while the rat has proven to be a useful animal model for investigations of cognition in a multitude of domains, caution must be taken when interpreting studies of PFC function in this subject as the homology between rodent and primate PFC is still a subject of debate (Uylings et al., 2003; Seamans et al., 2008). While it is important to view the following data with these considerations, it is also important to acknowledge the contribution of these data to our current understanding of serial order memory.

In an effort to substantiate findings of impaired serial order memory in human subjects following frontal lobe damage, Kesner and Holbrook (1987) designed a series of serial order assessments for rats utilizing spatial position in an eight-arm radial maze. The development of this adaptation, whereby spatial position was utilized as an identifier enabled the first studies of serial order memory in the rat. Mirroring findings in human subjects with lesions of the dlPFC, this study demonstrated that lesions of the medial PFC, in the rat, were sufficient to impair serial order memory, which was later confirmed in a study by Chiba et al. (1997). Specifically, the authors examined the performance of rats on both novel and repeated order spatial sequences. Interestingly, while medial prefrontal cortical lesioned subjects were impaired on both sequences, the magnitude of impairment was diminished in the repeated sequences. One possible explanation for the reduced impairment of repeated sequences is that repetition of the sequence allowed the information to be transferred into an alternative memory store, which may not be dependent upon the functional integrity of the medial PFC.

Given the absence of data detailing the impact of selective hippocampal lesions on serial order performance in primates, any information that the rodent data could provide on this topic is even more valuable. While it might have been expected that hippocampal lesions would impair serial order memory performance to some degree, the results of this study indicated that the serial order impairment following hippocampal lesions was more severe than that observed following the medial prefrontal cortical lesions (Chiba et al., 1994). While one could argue that the observed impairment on the serial order memory task was due to the spatial component of the task, a variation of the serial order memory task that used odor instead of spatial position mitigates this possibility (Kesner et al., 2002).

Conclusion and Future Directions

The fundamental goal of this article was to try to connect what is known about the basis of serial order memory, specifically the neural substrates that support and regulate its function across studies of humans, monkeys, and rodents. At its core, the capacity of an organism to monitor sequential events, be it their own actions or changes in their environment, is a critical function of species survival and proliferation. While not overemphasizing the importance of serial order memory, it is hard to imagine functioning successfully in the world without this capacity.

In examining the literature from the early studies of Jacobsen (1935) to the more recent developments of automated assessments of multiple-item serial order memory (Templer and Hampton, 2013), it is clear that there is a lot that remains to be explored in terms of the basis of serial order memory. At present, while it is reasonable to assert that the dlPFC is the functional locus of serial order memory, the contributions of other brain structures in serial order memory remain largely unknown.

Abstract

The term 'serial verb construction' is applied to a range of apparently similar syntactic constructions in different languages, which have in common the fact that they contain two or more verbs within a single phrase or clause, without overt signs of coordination. This article discusses problems of identification and description of serial verbs, their distribution in the world's languages, some competing syntactic analyses, the range of semantic functions which serial verbs perform, their importance in the field of Creole studies, and the historical development of 'serial verbs' into members of other syntactic categories such as prepositions and complementizers.

Definition and Importance

The term 'serial verb construction' (SVC) is usually applied to a range of apparently similar syntactic constructions in different languages, in which several verbs occur together within one clause or unit, without evidence of either subordination or coordination of the verbs. For example, sentences like (1), from the West African language Twi, are typical of what most scholars would regard as an SVC:

(1) Kofi de pono no baae
Kofi take-PAST table the come-PAST
'Kofi brought the table' or more literally,
'Kofi took the table and came with it'

SVCs have attracted attention from linguists for three main reasons. First, syntacticians have found them interesting because the possibility of having more than one main (i.e., nondependent, nonauxiliary) verb within a clause or clause-like unit challenges traditional assumptions that a clause contains exactly one predicate (see Foley and Olson, 1985: pp. 17, 57). Second, because of their prevalence both in languages of West Africa and in certain Creole languages, they have become central to debates among Creole language researchers, being seen either as evidence for the importance of substrate (i.e., African mother-tongue) influence on the Creole, or as deriving from universal properties of human language which are manifested in the creolization process (*see* Pidgin and Creole Language Varieties). Third, serial verbs show a tendency to be reanalyzed as other grammatical categories (complementizers and prepositions), with implications for the processes of historical change.

While different researchers use different criteria for defining serial verbs, the following set would probably be accepted by most and is based on one described by McWhorter (1997: p. 22) as a "relatively uncontroversial distillation of the conclusions of various scholars":

(2) (a) an SVC contains only one overt subject;
(b) it contains no overt markers of coordination or subordination;
(c) it expresses concomitant actions (either simultaneous or consecutive) or a single action;
(d) it falls under one intonational contour;
(e) it has tense–modality–aspect marking on none of the verbs, or on one only (usually the first or last in the series) or on all of them; and
(f) it contains a second verb, which is not obligatorily subcategorized for by the first verb.

Even the above six conditions leave it unclear where exactly to draw the line around SVCs, particularly in languages which have little morphology. In some cases of what may appear to be SVCs, we may be dealing simply with unmarked coordination of verb phrases expressing simultaneous actions.

Serial Verb Types

Serial constructions can be classified into different types on the basis of the functions of the verbs in the series relative to one another.

The sentences in (3) provide examples of different functional types of SVC which have been discussed in the literature.

(3) (a) *Directional complements*: V_2 is *go*, *come*, or another common intransitive motion verb which functions to indicate the directionality of the action denoted by V_1.
Olú gbé àga wá
Olu take chair come
'Olu brought a chair' (Yoruba, West African)

(b) *Other motion verb complements*: similar to type (a), but V_2 may be transitive motion verb with its own object expressing the goal of the action denoted by V_1
Kofi tow agyan no wɔɔ Amma
Kofi throw-PAST arrow the pierce-PAST Amma
'Kofi shot Amma with the arrow'

(c) *Instrumental constructions*: V_1 is *take* or a semantically similar common verb, while V_2 denotes an action performed with the aid of the object of V_1.
Kofi teki a nefi koti a brede
Kofi take the knife cut the Bread
'Kofi cut the bread with a knife' (Sranan, Caribbean Creole)

(d) *Dative constructions*: V_2 is usually *give*, with an object which denotes the (semantic) indirect object of V_1.

Ogyaw ne sika mãã me
he-leave-PAST his money give-PAST me
'He left me his money' (Twi, West African)

(e) *Comparative constructions*: a verb meaning *pass* or *surpass* is used with an object to express comparison. In this case 'V_1' is often in fact an adjective.
Amba tranga pasa Kofi
Amba strong pass Kofi
'Amba is stronger than Kofi' (Sranan, Caribbean Creole)

(f) *Resultative constructions*: V_2 denotes the result or consequence of an action denoted by V_1.
Kofi naki Amba kiri
Kofi hit Amba kill
'Kofi struck Amba dead' (or more literally, 'Kofi hit Amba and killed her') (Sranan, Caribbean Creole)

(g) *Idiomatic constructions* (*lexical idioms*): These are cases where the meaning of the verbs together is not derivable from the meanings of the verbs separately. They are not found in all serializing languages, but some of the West African group are particularly rich in them.
Anyi-Baule (West African):
bɔ 'hit' nĩã 'look' bɔ…nĩã 'say, tell'
Yoruba (West African):
là 'cut open' yé…'understand' là…yé 'explain'

Distribution in the World's Languages

Serial verb constructions have been identified in many languages but it is clear that they occur in areal clusters and are not spread evenly among the languages of the world. So far serializing languages have been identified in the following areas: West Africa (Kwa and related language families), the Caribbean (Creole languages which have a historical relationship with Kwa languages), Central America (e.g., Misumalpan), Papua New Guinea (Papuan languages and Tok Pisin Melanesian Pidgin English), South-east Asia (e.g., Chinese, Vietnamese, Thai). There are isolated reports of SVC-like constructions from elsewhere. How credible these are depends on which criteria are adopted to define SVCs.

Grammatical Analyses

Numerous researchers have put forward proposals for grammatical analyses of SVCs. The analyses may be classified into two types, with some degree of overlap. *Semantic* analyses typically seek to account for SVCs in terms of how they break down verbal concepts into more basic semantic components (take–carry–come for *bring*, for example). *Syntactic* analyses differ mainly according to whether they treat SVCs as a phrase structure phenomenon (usually under a version of X-bar theory), as a form of complementation, subordination, or secondary predication (i.e., involving more than one clause-like unit), or as a lexical phenomenon (e.g., as single but disjoint lexical items).

The following phrase structure (4) proposed for SVCs in the literature is typical of those advocated by a number of researchers:

(4) VP → V XP VP where X is N or P

This produces a right-branching tree with a theoretically infinite number of verbs in a series. Such a structure would allow lexical relations and relations like 'subject-of,' and 'object-of,' to hold between verbs in the series, and captures the intuition that verbs (or verb phrases) function as complements to verbs earlier in the sequence.

Some researchers have treated SVCs as involving complementation or subordination, with clauses or clause-like units embedded within the VP and dependent on a higher verb. For example, Larson (1991: pp. 198–205) has argued in favor of analyzing serial constructions as a case of 'secondary predication.' A structure similar to that for *Carol rubbed her finger raw* in English can also, he says, account for serial combinations of the *take…come* and *hit…kill* types – (a) and (f) above.

Foley and Olson (1985) propose a distinction between 'nuclear' and 'core' serialization. In nuclear serialization the serial verbs all occur in the nucleus of the clause, in other words the verbs form a single unit, which must share arguments and modifiers. The core layer of the clause consists of the nuclear layer plus the core arguments of the verb (Foley and Olson, 1985: p. 34). In 'core' serialization, two cores each with own nucleus and arguments, are joined together. Languages may exhibit both kinds of serialization or just one. Examples (a) and (b) below (Foley and Olson, 1985: p. 38) illustrate this difference; (a) is an example of core, and (b) of nuclear, serialization:

(5) (a) fu fi fase isoe
he sit letter write
'He sat down and wrote a letter' (Barai, Papuan)
(b) Fu fase fi isoe
He letter sit write
'He sat writing a letter'

This evidence suggests that 'serialization' may not be a unitary phenomenon, and although a single account which explains the two or more different construction types (such as Foley and Olson's) would be welcome, it may be that separate analyses may be needed as more different types of SVC come to light.

The Creolists' Debates

SVCs are among the most salient grammatical features of many Creoles of the Caribbean area, which distinguish them grammatically from their European lexifier languages. As such they have attracted attention from creolists, who, finding similar structures in West African languages which historically are connected with the Creoles in question, have claimed SVCs are evidence of substrate influence on the grammar of the Creoles concerned.

An alternative view has been offered by Bickerton (1981) and Byrne (1987), who regard the similarities between SVCs in the Creole and West African languages as coincidental. Instead, they argue, SVCs result in Creoles from universal principles of grammar, and are a consequence of the rudimentary verbal structure (V but not VP) which exist, they say, in a Creole at the earliest stage of development. They point out the existence of SVCs or serial-like structures in other pidgins and Creoles such as Tok Pisin (New Guinea Pidgin) and

Hawaiian Creole English, which have no historical connections with West Africa.

McWhorter (1997) argues against Bickerton and Byrne, claiming that the Caribbean Creoles not only share SVCs with West African languages, but that their SVCs are structurally similar to each other in ways that SVCs from other areal language groupings are not. Using the nuclear/core distinction proposed by Foley and Olson (see above), he argues that Papuan languages serialize at the nuclear level, while Kwa languages, Caribbean Creoles, Chinese, and other Southeast Asian languages serialize at the core level. Considering also the range of pidgins and Creoles, which lack SVCs altogether, he concludes that "SVCs have appeared around the world in precisely the creoles which had serializing substrata" (1997: p. 39).

SVCs have thus become a major site of contention between 'substratists' and 'universalists' in Creole studies, with both sides remaining committed to their own positions (*see* Pidgin and Creole Language Varieties).

SVCs and Language Change

Particular verbs which participate in serial constructions in some cases appear to have been reanalyzed as members of another syntactic category, e.g., from verb to preposition *(give → for)* or complementizer (*say → that*). In such cases, the position of the verb usually makes it amenable to such a reanalysis (e.g., if it typically occurs immediately before its objects, it may be reanalyzed as a preposition if the semantics encourage this interpretation). Reanalyzed serial verbs lose, to varying degrees, their verbal properties and take on, again to varying degrees, the morphological characteristics of their new category. Lord (1973) describes cases of reanalysis of verbs as prepositions, comitative markers, and a subordinating conjunction in Yoruba, Gã, Ewe, and Fon. Verbs with the meaning '*say*' are susceptible to reinterpretation as complementizers (introducing sentential clauses), while those with the meaning '*finish*' have a tendency to be interpreted as completive aspect markers (*see* Grammaticalization).

Related Constructions

Lack of a satisfactory definition of 'serial verb construction' makes it difficult to decide what may count as a related kind of structure. Chinese has a range of verbal structures which bear resemblances to SVCs. One of these, the class of *co-verbs*, is widely believed to be the result of the reanalysis of serial verbs as prepositions. Others, so-called *resultatives*, resemble secondary predications.

The Bantu languages, though related to the serializing languages of West Africa, do not seem to have SVCs. However, some have verbal chains where the second and subsequent verb have different marking from the first. In many Bantu languages, the verb meaning *say* is homophonous with a complementizer. These phenomena remain to be explained by a general theory.

Abstract

This article considers the development and role of services in the economy, the spatial relations of services as workplace and infrastructure. Topics include how services are organized and positioned in production systems, spatially distributed and operate across space. This article illustrates and reflects on the key question for service research in geography, namely the relationships between (1) integrating the practice of face-to-face service operations with partners and (2) providing services over distance and different locations (urban and rural, domestic and foreign) through the means of information and communication technology (ICT). The article concludes with an outlook on future research directions; clearly, service research reflects major societal issues and discourses, including new financial models, innovation, and environmental projects.

Three main sections follow: Part 1 is a broad discussion of the definitions and economic role of services; Part 2 focuses on producer services emphasizing position, development and roles in production systems; and Part 3 offers a discussion of recent research areas and prospects for future research on services.

Part 1. The Wider Setting

Conceptual Approach

Prompted by the deindustrialization of Western economies, research published in the 1970s attempted to capture key elements of the rapid and substantial growth of the service sector. Researchers in this area proposed several definitions of services; for example,

> Production of "goods" results in a material product that is typically storable and transportable. Production of "services" results in an output that is not storable and usually requires direct interaction with the customer. (Stanback, 1979: p. 5)

Hill's (1977) definition of services from the same period emphasizes the processes and effects of service activities. "A service may be defined as a change in the condition of a person or a good belonging to some economic unit, which is brought about as the result of the activity of some other economic unit, with the prior agreement of the former person or economic unit" (Hill, 1977: p. 318).

These definitions share an understanding of the direct, personal interactions that occur between service providers and clients. This process of coproduction involves "embodied expertise and emotional labor" (Bryson, 2007), which implies that services occur mainly in local markets, where face-to-face interactions are possible. In general, spatial relations in the provision of services are related to services' intangible features, namely whether a service is transportable through information and communications technology (ICT) modes or must be provided through face-to-face interactions. ICTs have drastically changed the market conditions concerning accessibility and exposure. This balance between requirements of *to be close* and *to be relatively insensitive to distance* is continuously changing and varies strongly among different types of service activities. This is also an issue that has attracted much research in geography.

One method researchers have approached the problem of understanding service sector has been to define the sector in terms of subcategories. Daniels (1985), for instance, used destination of output (producer or consumer services), type of occupation (white-collar or blue-collar), and organizational form (public or private). Also mentioned should be the conventional categorizations resembling templates for statistical classifications. Examples include "distributive services (communication, trade, transport); producer services (banking, business services, real estate); social services (education, health, postal services, public and nonprofit services) and personal services (hotels, repairs, restaurants, travel and others)" (Singelmann, 1978; Browning and Singelmann, 1975). Of these four categories, producer services, in particular, have received a great deal of research attention (e.g., Bryson and Daniels, 2007). Accordingly, one main section of this article is devoted to this segment of services, with particular emphasis on advanced producer services (APSs). Service sectors such as finance, retail, and cultural sectors are included in other articles in this encyclopedia and therefore are treated here only in summative terms.

Finding a comprehensive definition of services has been a less prominent concern in the more recent literature. Instead, the service approach argues for more integrated perspectives based on the assumption that services are activities integrated into all types of industries, regardless of the industrial sector. Arguments based on theories of service-dominated logics (Vargo and Lusch, 2008) and 'servification' of economic activities characterize many studies (Toivonen and Tuominen, 2009). Integrated perspectives have also been mentioned in discussions about combining a focus on knowledge-intensive business services (KIBS) bought in the market with knowledge-intensive service activities that may take place within the firm (Aslesen and Isaksen, 2007).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72050-2

Traditional production companies that no longer make their products in-house but instead purchase all production capacity from others are a further example of how the distinction between manufacturing and services is unclear. Yet, a different definitional approach that could bring fruitful insight to service research would be to change the traditional focus seen from the lens of the service provider to the lens of the customer (Edvardsson et al., 2005).

The Role of the Service Industry in the Economy

Increasing research on the service sector signals the increasing importance of such economic activities. One direct (and readily observed) impact is the dominance of the service sector in the job market. If we examine Western industrial economies and the structure of the job market, we can see that the United States was a forerunner in restructuring to a service economy. Since the mid-1960s, service jobs have come to dominate, gradually transforming Western countries into service economies (Daniels, 1985). This shift includes both commercial and public sectors.

Figure 1 illustrates the proportion of jobs in the service sector for a selection of Organization for Economic Cooperation and Development (OECD) countries. It includes the countries with the highest (80% or more) and lowest percentage of workers in the service sector. Those countries with the highest percentage of service jobs include smaller economies such as Luxembourg and the Netherlands, as well as large economies such as the United States and the United Kingdom. OECD countries with the smallest percentage of jobs in the service sector include former Eastern Bloc countries and Turkey. On an average, 72% of the jobs in OECD countries are service jobs.

Most research on services has been based in the empirical context of the older industrialized economies. As services have more recently expanded in Asia, so has research interest shifted in empirical focus (e.g., Daniels et al., 2005; Park, 2006; Ström, 2005, 2006).

There are doubts about the benefits of such expansion of increasingly service-oriented economies. First, there are arguments concerning limited productivity growth in service-dominated economies. If services are coproduced in face-to-face interactions, it is difficult for productivity to grow and eventually the growth getting difficult to measure. However, the organizational forms for the production and distribution of services vary immensely and there are service activities with strong, measurable productivity growth. Such services include standardized operations that have been able to replace staff with computers in recent years (banks, retail, travel and transportation, etc.) (Bryson et al., 2004: pp. 20–21).

Other doubts about the benefits of service-based economies center on the tradability constraints with limited value as an export industry. The concern is that the changing balance between manufacturing and services (with the service sector predominating) threatens the overall export volume of national economies. However, this line of reasoning is empirically untrue. Over time, service companies have developed into major transnational corporations doing international business. Over half of the companies on the Forbes Global 2000 list (the world's largest public companies) are in the service industry segment. Banking and other financial services companies dominate the list, with more than 500 companies. Other service industries with more than 50 major international companies on the list are retail, transportation, construction, telecommunications, media and business services. Other categories of companies cut across the service–manufacturing divide, such as health care equipment and services, with more than 50 major global companies on the list.

Although tradability in the service industry has increased substantially, this increase does not fully correspond to the growing role this sector plays in the economy in terms of its share of GDP or employment. In OECD countries in 2008, exports of services were 23% of all exports (OECD/Eurostat, 2011).

Figure 1 Percentage of workforce employed in services in a selection of OECD countries in 2011. Source: OECD Statistics OECD StatExtracts/Short-Term Labour Market Statistics. http://stats.oecd.org/Index.aspx?DataSetCode=STLABOUR.

Many different and mutually reinforcing factors are behind the internationalization of services (Daniels, 1993). These factors include the political liberalization and disappearance of national barriers to different types of international exchange (financial capital, direct investments, commodities, labor, etc.), standardization, the development of ICTs to facilitate communication and monitor spatially dispersed organizations, networks and relationships between suppliers and clients. The extent to which services are ICT-mediated and ICT-coded in a digital form further enhances their suitability for international markets (Bryson, 2007). This development leads to a discussion about the international division of labor for service tasks and about organizational forms that include offshoring or global sourcing.

As the discussion above indicates, the service industry contributes to the job market, to export incomes, and to the economy as a whole. In addition, more qualitative discussions cite the importance of the service industry (via the effects of its output) for regional development. For instance, service providers can increase the productivity and improve the competence of their clients' firms, as well as facilitate specialization of production networks. Firms in various sectors can also use services as a tool to differentiate their offerings from those of competitors (Kujala et al., 2013).

From a production network perspective, the growth of service jobs or service firms is partly an illusion in that, rather than being produced in-house, services are provided by external suppliers. This raises the issue of outsourcing, through which firms "switch from internal sourcing of inputs to external independently owned providers" (Bryson, 2007: p. 31) However, increased externalization of services is not just a matter of reorganization. Increased demand also relates to the recent demand for different types of services. Increasing complexity, technological developments, competition, expectations, and spending power in a globalized economy are all processes that explain this development. This applies to ICT services, education services and management, among other specialized and more routinized services.

The Service Industry, Uneven Development, and Regional Specialization

Although the expansion of the service industry to the international scale is an important trend, some services, including many consumer services and public sector services, cater to primarily local or regional markets. With spatial distributions that mimic the population settlement pattern, such services make important contributions to local and regional job markets. Other service activities, including APSs and public services, are mainly concentrated in larger urban areas. Such services were the focus of office location research in the 1970s, which investigated, inter alia, office relocation possibilities away from southeast England, a 'hot' issue because of the urban congestion and concomitant diseconomies of scale in London (e.g., Goddard, 1975; Daniels, 1979). More recently, authors have discussed the emergence of knowledge-intensive and creative industries in inner cities (Hutton, 2004). Studies have also illustrated the suburbanization of services along major infrastructure systems following the increasing costs for such services in city centers (e.g., Hermelin, 2007; Illeris, 1997).

Research in the United States on rural-based advanced services includes work on classic self-employed (Lone Eagles) and small (High Flyers) firms (Beyers and Lindahl, 1996). Such firms may operate from home with service clients all over the United States and abroad. Their means of operation include online communication as well as site visits to their clients' firms. Some home-based service firms examined in this work also had an urban office address that the owners visited from time to time. In South Korea, Park (2006) examined how self-employed experts form virtual teams, selected to match the needs of their clients in different locations. The regional specialization of international industries is another example of how client hot spots for services can occur outside of large urban areas (Bryson and Rusten, 2005).

Recent studies have also problematized theories of geographic clustering and innovation capacities, which maintain that innovation requires the colocation of actors and resources. The spatiality of innovation processes has different geographies in different types of milieus, such as metropolitan or more sparsely populated and remote regions (Doloreux and Shearmur, 2012).

Labor Force

Labor is the main resource and capital of service companies. The educational background of employees in service industries varies from relatively little education in the retail and transportation industries to high average levels in sectors such as business services, finance, and public administration. Relative to workers in insecure and temporary jobs, the service work force comprises some of the most privileged segments of the labor market in terms of incomes and other fringe benefits.

Highly competitive service companies and service functions, such as call centers, look for low-cost labor. The cost of labor varies among locations and may relate to aspects of workers such as gender. Low-skilled labor-oriented industries and activities faced with fierce price competition have produced a labor market with poorly paid workers and insecure jobs (Tickell, 1999).

Linda McDowell has elaborated on how service jobs involve different aspects of bodily performance and what is termed 'bodywork': "From sex work, through elder care to university teaching, an embodied performance is a central part of the exchange" (McDowell, 2009: p. 64). This embodiment of work typically means face-to-face interactions between workers and customers that require emotional labor. The example of 'empathetic' women workers in health care illustrate the gendered understanding of care delivered by female workers in the emotional work sector.

Research on the international trade of services has also focused on specific service experts, including work on expatriation in professional legal firms (Beaverstock, 2004) and studies of international law firms and their work and communication arrangements (Jones, 2007). It also includes research on growth strategies and modes of entry in a study of global headhunting firms (Faulconbridge et al., 2008) and studies of advertising firms operating

on different geographical levels in relationship with clients (Hermelin, 2009).

Part 2. Advanced Producer Services in Focus

High-order or APSs are widely acknowledged to contribute to the creation of wealth in an economy. Although the definition of APS varies, it is possible to find common ground as summarized by Beyers (2001): "Business, legal, and engineering and management services are included in most studies, while the financial services are often considered to be part of the producer services. It is less common to consider services to transportation, wholesaling and membership organizations as a component of the producer services" (p. 13930). Different authors also use different labels for this sector, sometimes equating it with the KIBS concept.

The main argument for the importance of APS is the increasing significance of knowledge, learning, and innovation in modern economies. APSs are important components in mediating, customizing, and developing knowledge and contributing to the learning process among client firms. KIBS are key constituents of innovation systems (Cooke and Leydesdorff, 2006) as well as key vectors of knowledge transmission (MacPherson, 2008). Though KIBS act as enablers, they are also innovators in their own right, developing new combinations of knowledge, services, ways of accessing markets, and ways of producing and delivering services (Miles, 1993).

ICT and Service Activities across Organizations and Space

ICT services, one sector of APS, is an important example on how such companies are important for innovations systems. ICTs provide organizations with a new type of flexibility in work arrangements (Coffey and Bailly, 1991). The ICT tool became a very efficient way for business to access information and communicate online across space.

Many innovations in services involve combinations of ICTs (e.g., ICT hardware, software, 3D scanners, webcameras, and smart boards) with organizational changes, including different types of self-service systems (e.g., automatic telling machines (ATMs), check-in systems at airports and tax reporting systems). This has resulted in more time-efficient and less labor-intensive operations, as well as in facilitating customer projects, design, distribution, reporting, training and control of data across systems, and geographical distances. The advent of 3D technologies for example, enables engineers, architects, and designers to better visualize products and thus to integrate their different areas of expertise more closely in tailoring the details of the production process (Rusten and Bryson, 2010).

Technological shifts in how services are organized have actually pushed some work from the service provider to the user. The implication of this technological rationalization is a drastic cut in number of service offices, such as bank units, travel agencies, and post offices. These cutbacks have also led to a more spatially centralized location pattern.

It is also important to address the interdependencies among technologically oriented innovation projects (innovations in services) and research and development, technological services, and Technology Transfer Organizations (services for innovation). The interdependencies do, for example, concern the forms and conditions of entrepreneurship and service innovations. Monnoyer-Longé (2010) uses empirical evidence from Toulouse to discuss the structure of these types of service firms and how firms are supported by the local economy. Related topics concern what parts of an innovation process are internal versus external to an organization, (Bryson and Monnoyer, 2002; Gallouj, 2002). Sundbo (1997) has studied the level of innovations and ways of organizing among service firms with empirical evidence from Denmark.

Outsourcing is about the transferring of in-house activities to external providers that may be geographically near or distant, and offshoring refers to those cases where the external providers are in another country. The occurrence of service offshoring expanded with the introduction of call centers in the 1970s and 1980s, but since then, such offshoring has come to involve more knowledge-intensive services. Programming, accounting services, engineering and medical diagnostic services can all be electronically transmitted over long distances. As a result, ICT enables organizations to become more flexible in how work is arranged spatially (Coffey and Bailly, 1991). In some cases, it was a way of cutting costs or getting around the problem with scarce local access of expertise (e.g., places with recruitment problems and dearth of local service providers).

Cost savings, a wish to focus on the core business and gaining access to additional capacity and competence are among the motivations for outsourcing or offshoring (Wernerheim, 2012). Internal service solutions and shared service centers are other examples of business models that offshoring vendors use in the spatial organization of these projects. Market trends influence the way businesses manage their operations. There are reasons to expect that continued development, adoption and integration of technologies would lead to increased offshoring, as more information is automated and digitized.

Geographers have examined the way client firms and service providers find each other. Sourcing strategies (such as where and how to search) are partly the result of internal structural elements, including motivation, knowledge, previous experience, and, above all, financial position. Rusten et al. (2005) explain how multisite companies that use a professional purchasing department for the whole company tend to weaken ties to local service providers that the local units of the company had established. Awareness of local qualities will be less evident if such a purchasing department is located elsewhere. These new forms of sourcing knowledge have eroded some of the obvious advantages associated with clusters as many services can easily be accessed from elsewhere. Yet another alternative is negotiating procurements through brokers. The broker may procure a single service or a bundle of different services packaged together. This bundle can be directly supplied by a single supplier or coordinated by a broker that chooses among different suppliers. Using a bundling strategy in bid announcements is a way to reduce the number of service providers and transfer some of the management costs in organizing such projects to a third party. Contractual issues

can include questions concerning the size, length, quality, responsibilities, and other details about the delivery of services. A further way of limiting the number of suppliers can be to group several sites under the same contract. The implication of winner that takes all is twofold. First, companies and areas receiving contracts may face capacity problems and need to increase their number of staff. Second, those that do not win contracts might have to reduce their staff or close their operations. Both effects will create a more unstable and unpredictable situation for the workforces and lead to greater mobility between companies and locations.

An important organizational reform that challenged the quality, efficiency, and division of labor between public and private services has been the modernization of the service sector with new public management (NPM). Starting in the United Kingdom and New Zealand in the beginning of the 1980s, NPM later spread to several other countries. The organizational changes this modernization brought expanded the field of business services to accommodate issues such as practice of tendering for bids, contract management, performance measurements, training, and legal matters. NPM research includes discussion about the efficiency of NPM reforms to rural areas (Hanlon and Rosenberg, 1998).

The Sarbanes–Oxley Act (SAX) came after the accounting scandal in the US service industries in 2001 (Enron, Arthur Andersen) and regulates all companies American and foreign that are listed on US stock exchanges. To avoid conflicts of interest and to increase transparency, this Act introduced several regulations to raise auditing standards and encourages organizational and legal separation between consulting and accounting services. In the same period, several mergers and acquisitions among multinational consulting firms created service providers with expertise in management and ICT (Bryson and Rusten, 2005). Examples are PricewaterhouseCoopers, sold to IBM in 2002, and several acquisitions within Cap Gemini and KPMG. A European version of SAX came with the 8th Company Law Directive in the European Union in 2006.

Another regulation that has promoted services was the Directive on Services in the Internal Market, which aimed to stimulate growth in the service industries in Europe by removing some legal and administrative barriers. The service directive includes a range of services to both business and private individuals, including business-related services, trade, food, and accommodation, but excluding finance, temporary agency services, temporary work agency services, and social services provided by the State (http://ec.europa.eu/internal_market/top_layer/services/index_en.htm). The list of services that were included and excluded once again challenges conventional conceptual understandings of services that undergirded research in this field. Figure 2 below describes major technological, organizational, and regulative changes that have challenged the conceptual understanding of services and have thrown up new issues for research.

Figure 2 Development of major factors forming the understanding of and research on services.

Part 3. Recent and Future Research Directions

Future directions for research can be traced through scholarly conferences and networks. In this context, the European Research Network on Services and Space (RESER), which was founded in Lyon in 1991 (Bonamy et al., 1993; http://www.reser.net/) is an important forum. Its annual conference is a meeting place for geographers, economists, and other social scientists conducting service research.

Recent publications in major journals of geography confirm the likely continuance of a focus on APSs although also less-established themes are represented. These upcoming fields also include discussions on new organizational forms like for-profit education services and joint projects of private and public sector organizations (Hall and Appleyard, 2011; Siemiatycki, 2012). Recently published articles on ecosystem services have also led discussions to address environmental policy more widely (e.g., Dempsey and Robertson, 2012). These examples will once again challenge our understanding about what services are.

Settlement and Landscape Archaeology

Gary M Feinman, The Field Museum, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Settlement pattern archaeology and the investigation of ancient landscapes, especially when systematically implemented, have been some of the most significant archaeological innovations of the last half century. These studies have shed new light on the emergence of hierarchically organized and urban societies in regions around the world, while also providing new perspectives on the history of human–environmental interactions. This article reviews the roots of these regional archaeological approaches, their theoretical underpinnings, and some of the key empirical contributions.

Settlement pattern and landscape approaches are central to the mission of contemporary archaeology (Kowalewski, 2008; Renfrew, 2003, p. 313; Sabloff and Ashmore, 2001, p. 14). Through archaeological surveys, they provide a regional perspective on behavioral change that has been key to the transition from normative to relational or populational perspectives on the past. Although these studies have had the greatest impact on the understanding of arid and semiarid areas, they have been employed under a range of conditions. There is no correct way to survey; however, methodological procedures and analytical strategies must be guided by environmental conditions, available resources, and research goals. The most successful studies to date have been those in which significant and sustained time and labor investments have been made.

For contemporary archaeology, settlement and landscape approaches represent an increasingly important focus that is vital for a core mission of the discipline to describe, understand, and explain long-term cultural and behavioral changes. Despite this significance, relatively few syntheses of this topic have been undertaken (cf Ammerman, 1981; Billman and Feinman, 1999; Fish and Kowalewski, 2009; Kowalewski, 2008; Parsons, 1972). Yet settlement and landscape approaches provide the only large-scale perspective for the majority of premodern societies. These studies are reliant on archaeological surface surveys, which discover and record the distribution of material traces of past human presence/habitation across a landscape (*see* Survey and Excavation (Field Methods) in Archaeology). The examination and analysis of these physical remains found on the ground surface (e.g., potsherds, stone artifacts, house foundations, or earthworks) provide the empirical foundation for the interpretation of ancient settlement patterns and landscapes.

Historical Background

Although the roots of settlement pattern and landscape approaches extend back to the end of the nineteenth century, archaeological survey has only come into its own in the post-World War II era. Spurred by the analytical emphases of Steward (1938), Willey's Virú Valley Archaeological Survey (1953) provided a key impetus for settlement pattern research in the Americas. In contrast, the landscape approach, which has a more focal emphasis on the relationship between sites and their physical environments, has its roots in the United Kingdom. Nevertheless, contemporary archaeological studies indicate a high degree of intellectual cross-fertilization between these different surface approaches.

Early Foundations for Archaeological Survey in the Americas and England

The American settlement pattern tradition stems back to scholars such as Morgan (1881), who queried how the remnants of Native American residential architecture reflected the social organization of the native peoples who occupied them. Yet the questions posed by Morgan led to relatively few immediate changes in how archaeology was practiced, and for several decades few scholars endeavored to address the specific questions regarding the relationship between settlement and social behavior that Morgan posed. When surface reconnaissance was undertaken by archaeologists, it tended to be a largely unsystematic exercise carried out to find sites worthy of excavation.

In the United Kingdom, the landscape approach, pioneered by Fox (1923), was more narrowly focused on the definition of distributional relationships between different categories of settlements and environmental features (e.g., soils, vegetation, and topography). Often, these early studies relied on and summarized surveys and excavations that were carried out by numerous investigators using a variety of field procedures rather than more uniform or systematic coverage implemented by a single research team. At the same time, the European landscape tradition generally has had a closer link to romantic thought as opposed to the more positivistic roots of the North American settlement pattern tradition (e.g., Sherratt, 1996).

The Development of Settlement Archaeology

By the 1930s and 1940s, US archaeologists working in several global regions recognized that changing patterns of social organization could not be reconstructed and interpreted through empirical records that relied exclusively on the excavation of a single site or community within a specific region. For example, in the lower Mississippi Valley, Phillips et al.

(1951) located and mapped archaeological sites across a large area to analyze shifting patterns of ceramic styles and settlements over broad spatial domains and temporal contexts.

Yet the most influential and problem-focused investigation of that era was that of Willey in the Virú Valley. Willey's project was the first to formally elucidate the scope and potential analytical utility of settlement patterns for understanding long-term change in human economic and social relationships. His vision moved beyond the basic correlation of environmental features and settlements as well as beyond the mere definition of archetypical settlement types for a given region. In addition to its theoretical contributions, the Virú program also was innovative methodologically, employing (for the first time in the Western Hemisphere) vertical air photographs in the location and mapping of ancient settlements. Although Willey did not carry out his survey entirely on foot, he did achieve reasonably systematic areal coverage for a defined geographic domain for which he could examine changes in the frequency of site types, as well as diachronic shifts in settlement patterns.

Conceptually and methodologically, these early settlement pattern projects of the 1930s and 1940s established the intellectual underpinnings for a number of multigenerational regional archaeological survey programs that were initiated in at least four global regions during the 1950s and 1960s. In many ways, these later survey programs were integral to the theoretical and methodological reevaluations that occurred in archaeological thought and practice under the guise of 'the New Archaeology,' or processualism. The latter theoretical framework stemmed in part from an expressed emphasis on understanding long-term processes of behavioral change and cultural transition at the population (and so regional) scale. This perspective, which replaced a more normative emphasis on archetypical sites or cultural patterns, was made possible to a significant degree by the novel diachronic and broad scalar vantages pieced together for specific areas through systematic regional settlement pattern fieldwork and analysis.

Large-Scale Regional Survey Programs

During the 1950s through the 1970s, major regional settlement pattern programs were initiated in the heartlands of three areas where early civilizations emerged (Greater Mesopotamia, highland Mexico, and the Aegean), as well as in one area known for its rich and diverse archaeological heritage (the Southwest United States). The achievements of the Virú project also stimulated continued Andean settlement pattern surveys, although a concerted push for regional research did not take root there until somewhat later (e.g., Billman and Feinman, 1999; Parsons et al., 1997).

Beginning in 1957, Robert M. Adams (e.g., 1965, 1981) and his associates methodically traversed the deserts and plains of the Near East by jeep, mapping earthen tells and other visible sites. Based on the coverage of hundreds of square kilometers, these pioneering studies of regional settlement history served to unravel some of the processes associated with the early emergence of social, political, and economic complexity in Greater Mesopotamia. Shortly thereafter, in highland Mexico, large-scale, systematic surveys were initiated in the area's two largest mountain valleys (the Basin of Mexico and the Valley of Oaxaca). These two projects implemented field-by-field, pedestrian coverage of some of the largest contiguous survey regions in the world, elucidating the diachronic settlement patterns for regions in which some of the earliest and most extensive cities in the ancient Americas were situated (e.g., Blanton et al., 1993; Sanders et al., 1979). After decades, about half of the Basin of Mexico and almost the entire Valley of Oaxaca were traversed by foot (Balkansky, 2006).

In the Aegean, regional surveys (McDonald and Rapp, 1972; Renfrew, 1972) were designed to place important sites with long excavation histories in broader spatial contexts. Once again, these investigations brought new regional vantages to areas that already had witnessed decades of excavation and textual analyses (Galaty, 2005). Over the same period, settlement pattern studies were carried out in diverse ecological settings across the US Southwest, primarily to examine the differential distributions of archaeological sites in relation to their natural environments, and to determine changes in the numbers and sizes of settlements across the landscape over time. More recently, new projects have introduced systematic, broad-coverage, archaeology settlement pattern studies to other regions, including parts of northern China (e.g., Feinman et al., 2010; Peterson et al., 2010; Underhill et al., 2008) and Madagascar (Wright, 2007). In each of the global areas investigated, the wider the study domain covered, the more diverse and complex were the patterns found. Growth in one part of a larger study area was often timed with the decrease in the size and number of sites in another. And settlement trends for given regions generally were reflected in episodes of both growth and decline.

Each of these major survey regions (including much of the Andes) is an arid to semiarid environment. Without question, broadscale surface surveys have been most effectively implemented in regions that lack dense ground cover, and therefore the resultant field findings have been most robust. In turn, these findings have fomented long research traditions carried out by trained crews, thereby contributing to the intellectual rewards of these efforts. As Ammerman (1981, p. 74) has recognized, "major factors in the success of the projects would appear to be the sheer volume of work done and the experience that workers have gradually built up over the years."

Settlement Pattern Research at Smaller Scales of Analysis

Although settlement pattern approaches were most broadly applied at the regional scale, other studies followed similar conceptual principles in the examination of occupational surfaces, structures, and communities. At the scale of individual living surfaces or house floors, such distributional analyses have provided key indications as to which activities (such as cooking, food preparation, and toolmaking) were undertaken in different sectors (activity areas) of specific structures (e.g., Flannery and Winter, 1976) or surfaces (e.g., Flannery, 1986, pp. 321–423). In many respects, the current emphasis on household archaeology (e.g., Santley and Hirth, 1993; Wilk and Rathje, 1982) is an extension of settlement pattern studies. Both household and settlement pattern approaches have fostered a growing interest in the nonelite sector of complex societies, and so have spurred the effort to understand societies as more than just undifferentiated, normative wholes.

At the intermediate scale of single sites or communities, settlement pattern approaches have compared the distribution of architectural and artifactual evidence across individual sites. Such investigations have clearly demonstrated significant intrasettlement variation in the functional use of space (e.g., Hill, 1970), as well as distinctions in socioeconomic status and occupational history (e.g., Blanton, 1978). From a comparative perspective, detailed settlement pattern maps and plans of specific sites have provided key insights into the similarities and differences between contemporaneous cities and communities in specific regions, as well as the elucidation of important patterns of cross-cultural diversity (e.g., Arnauld et al., 2012).

Contemporary Research Strategies and Ongoing Debates

The expansion of settlement pattern and landscape approaches over the last decades has promoted the increasing acceptance of less normative perspectives on cultural change and diversity across the discipline of archaeology. In many global domains, archaeological surveys have provided a new regional-scale (and in a few cases, macroregional-scale) vantage on past social systems. Settlement pattern studies also have yielded a preliminary means for estimating the parameters of diachronic demographic change and distribution at the scale of populations, something almost impossible to obtain from excavations alone. Nevertheless, important discussions continue over the environmental constraints on implementation, the relative strengths and weaknesses of different survey methodologies, issues of chronological control, procedures for population estimation, and the appropriate means for the interpretation of settlement pattern data.

Environmental Constraints

Although systematic settlement pattern and landscape studies have been undertaken in diverse environmental settings including heavily vegetated locales such as the Guatemalan Petén, the eastern woodlands of North America, and temperate Europe, the most sustained and broadly implemented regional survey programs to date have been enacted in arid environments. In large part, this preference pertains to the relative ease of finding the artifactual and architectural residues of ancient sites on the surface of landscapes that lack thick vegetal covers. Nevertheless, archaeologists have devised a variety of means, such as the interpolation of satellite images, the detailed analysis of aerial photographs, and subsurface testing programs, that can be employed to locate and map past settlements in locales where they are difficult to find through pedestrian coverage alone (e.g., Chase et al., 2012). In each study area, regional surveys also have to modify their specific field methodologies (the intensity of the planned coverage) and the sizes of the areas that they endeavor to examine to the nature of the terrain and the density of artifactual debris (generally nonperishable ancient refuse) associated with the sites in the specified region. For example, sedentary pottery-using peoples generally created more garbage than did mobile foragers; the latter usually employed more perishable containers (e.g., baskets and cloth bags). Consequently, other things being equal, the sites of foragers are generally less accessible through settlement and landscape approaches than are the ancient settlements that were inhabited for longer durations (especially when ceramics were used).

Survey Methodologies and Sampling

Practically since the inception of settlement pattern research, archaeologists have employed a range of different field survey methods. A critical distinction has been drawn between full-coverage and sample surveys. The former approaches rely on the complete and systematic coverage of the study region by members of a survey team. To ensure the full coverage of large survey blocks, team members often space themselves 25–50 m apart, depending on the specific ground cover, the terrain, and the density of archaeological materials. As a consequence, isolated artifact finds can occasionally be missed. But the researchers generally can discern a reasonably complete picture of settlement pattern change across a given region. Alternatively, sample surveys by definition are restricted to the investigation of only a part of (a sample of) the study region. Frequently, such studies (because they only cover sections of larger regions) allow for the closer spacing of crew members.

Archaeologists have employed a range of different sampling designs. Samples chosen for investigation may be selected randomly or stratified by a range of diverse factors, including environmental variables. Nevertheless, regardless of the specific sampling designs employed, such sample surveys face the problem of extrapolating the results from their surveyed samples to larger target domains that are the ultimate focus of study. Ultimately, such sample surveys have been shown to be more successful at estimating the total number of sites in a given study region than at defining the spacing between sites or at discovering rare types of settlement. The appropriateness of sample design can be decided only by the kinds of information that the investigator aims to recover. There is no single correct way to conduct archaeological survey, but certain methodological procedures have proved more productive in specific contexts and given particular research aims.

Chronological Constraints and Considerations

One of the principal strengths of settlement pattern research is that it provides a broadscale perspective on the changing distribution of human occupation across landscapes. Yet the precision of such temporal sequences depends on the quality of chronological control (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology). The dating of sites during surveys must depend on the recovery and temporal placement of chronologically diagnostic artifacts from the surface of such occupations. Artifacts found on the surface usually are already removed from their depositional contexts. Finer chronometric dating methods generally are of little direct utility for settlement pattern research, since such methods are premised on the recovery of materials in their depositional contexts. Of course, chronometric techniques can be used in more indirect

fashion to refine the relative chronological sequences that are derived from the temporal ordering of diagnostic artifacts (typically pottery).

In many regions, the chronological sequences can be refined only to periods of several hundred years in length. As a result, sites of shorter occupational durations that may be judged to be contemporaneous in fact could have been inhabited sequentially. In the same vein, the size of certain occupations may be overestimated as episodes of habitation are conflated. Although every effort should be made to minimize such analytical errors, these problems in themselves do not negate the general importance of the long-term regional perspective on occupational histories that in many areas of the world can be derived from archaeological survey alone. Although the broad-brush perspective from surveys may never provide the precision or detailed views that are possible from excavation, they yield an encompassing representation at the population scale that excavations cannot achieve. Adequate holistic perspectives on past societies rely on the multiscalar vantages that are provided through the integration of wide-ranging archaeological surveys with targeted excavations.

Population Estimation

One of the key changes in archaeological thought and conceptualization over the past half century has been the shift from essentialist/normative thinking about ancient societies to a more populational perspective. But the issue of how to define past populations, their constituent parts, and the changing modes of interaction between those parts remains challenging at best. Clearly, multiscalar perspectives on past social systems are necessary to collect the basic data required to estimate areal shifts in population size and distribution. Yet considerable debate has been engendered over the means employed by archaeologists to extrapolate from the density and dispersal of surface artifacts pertaining to a specific phase to the estimated sizes of past communities or populations.

Generally, archaeologists have relied on some combination of the empirically derived size of a past settlement, along with a comparative determination of surface artifact densities at that settlement, to generate demographic estimates for a given community. When the estimates are completed for each settlement across an entire survey region, extrapolations become possible for larger study domains. By necessity, the specific equations to estimate past populations vary from one region to another because community densities are far from uniform over time or space (e.g., Fang et al., 2004). Yet due to chronological limitations, as well as the processes of deposition, disturbance, and destruction, the techniques for measuring ancient populations remain coarse-grained. Although much refinement is still needed to translate survey data into quantitative estimates of population with a degree of precision and accuracy, systematic regional surveys still can provide the basic patterns of long-term demographic change over time and space that cannot be ascertained in any other way.

The Interpretation of Regional Data

Beyond the broad-brush assessment of demographic trends and site distribution in relation to environmental considerations, archaeologists have interpreted and analyzed regional sets of data in a variety of ways. Landscape approaches, which began with a focused perspective on humans and their surrounding environment, have continued in that vein, often at smaller scales. Such studies often examine in detail the placement of sites in a specific setting with an eye toward landscape conservation and the meanings behind site placement (Sherratt, 1996). At the same time, some landscape studies have emphasized the identification of ancient agrarian features and their construction, use, and long-term implications for anthropogenic environmental impacts (e.g., Fisher et al., 2009).

In contrast, other settlement pattern investigations have employed a range of analytical and interpretive strategies. In general, these have applied more quantitative procedures and asked more comparatively informed questions. Over the last 40 years (e.g., Johnson, 1977), a suite of locational models derived from outside the discipline has served as guides against which different sets of archaeological data could be measured and compared. Yet debates have arisen over the underlying assumptions of such models and whether they are appropriate for understanding the preindustrial past. For that reason, even when comparatively close fits were achieved between heuristically derived expectations and empirical findings, questions regarding equifinality (similar outcomes due to different processes) emerged. More recently, theory-building efforts have endeavored to rework and expand these locational models to specifically archaeological contexts with a modicum of success. Continued work in this vein, and the integration of some of the conceptual strengths from both landscape and settlement pattern approaches are requisite to understanding the complex web of relations that govern human-to-human and human-to-environment interactions across diverse regions over long expanses of time.

Looking Forward: The Critical Role of Settlement Studies

The key feature and attribute of archaeology is its long temporal panorama on human socioeconomic formations. Understanding these formations and how they changed, diversified, and varied requires a regional/populational perspective (as well as other vantages at other scales). Over the last century, the methodological and interpretive tool kits necessary to obtain this broadscale view have emerged, diverged, and thrived. The emergence of archaeological survey (and settlement pattern and landscape approaches) has been central to the disciplinary growth of archaeology and its increasing ability to address and contribute to questions of long-term societal change. Why and how did inequality, demographic nucleation, and concentrations of political power become central to the current human career (*see* States and Civilizations, Archaeology of) and in what ways did these historical processes differ and parallel each other across the globe (e.g., Peterson and Drennan, 2012; Smith et al., 2012).

Yet settlement pattern work has only relatively recently entered the popular notion of this discipline, long wrongly equated with and defined by excavation alone. Likewise, many archaeologists find it difficult to come to grips with

a regional perspective that has its strength in (broad) scalar representation at the expense of specific reconstructed detail. Finally, the potential for theoretical contributions and insights from settlement pattern and landscape approaches (and the wealth of data collected by such studies) has only scratched the surface. In many respects, the growth of regional survey and analysis represents one of the most important conceptual developments of twentieth-century archaeology. Yet at the same time, there are still so many mountains (literally and figuratively) to climb.

Sex Crimes

Mary A Finn and Sebastian Czech, Georgia State University, Atlanta, GA, USA

Abstract

The definitions, nature, and extent of sex crimes committed against adults (rape/sexual assault and sex trafficking/prostitution) and children (sexual abuse, incest, pedophilia, and child sex trafficking) are presented. Three common explanations for sex offending are provided: feminist theory of rape, economic theory of sex trafficking, and pathological/individualistic explanations of child sexual abuse. Emerging research areas on juvenile sex offenders and female sex offenders, as well as sex offending in the contexts of the military, on college campuses, and in correctional settings (prisons, jails, juvenile confinement facilities) are presented.

Introduction

Sexual victimization of adults and children is a complex and universal problem that occurs in multiple cultures and societies. For both child and adult victims of sex crimes, involvement in sexual activity is unwanted or forced in order to satisfy another person's sexual gratification, need for power and control, or financial benefit. Information on the prevalence and incidence of sex crimes, whether collected through surveys of community or from official reports of victimization, underestimate the true extent of the phenomenon. The majority of perpetrators of sex crimes know their victims, and females are more likely to be victims and males more likely to be perpetrators, regardless of the age of the victim. The explanations for sex offending are varied, often dependent upon the sexual maturity (age) of the victims. Most recently, research attention has shifted to examining sex offending by women and by youth, and federal legislation has been enacted to address the extent of sexual assaults that occur in institutional settings, such as the military, college campuses, and correctional institutions.

Sex Crimes: Definitions, Nature, and Extent

Sex Crimes against Children

Protection of children from sexual abuse and other types of maltreatment is the joint responsibility of state child protection and law enforcement agencies. Sexual abuse is defined as the "involvement of the child in sexual activity to provide sexual gratification or financial benefit to the perpetrator, including contacts for sexual purposes, molestation, statutory rape, prostitution, pornography, exposure, incest, or other sexually exploitive activities" (U.S. Department of Health and Human Services, 2012: 125). Most states have laws that mandate certain professionals and institutions report suspected child abuse/neglect to appropriate legal authorities. As such, the action or inaction of parents and caretakers are the focus of such laws, and intervention efforts of child protection agencies include prevention of maltreatment and family preservation. However, not all abuse suffered by children is perpetrated by their parents or caretakers, but is instead perpetrated by peers, strangers, or acquaintances. If child abuse persists or worsens in the home, or if child abuse is perpetrated by someone outside the family, criminal charges may be levied. Thus, information on sexual victimization of children is available from reports made to child protection agencies and from official records of police, prosecutors, and courts.

The widespread prevalence of child sexual abuse internationally was documented initially by Finkelhor (1994) and more recently by Pereda et al. (2009). Child sexual abuse is a significant public health problem. Few epidemiological studies have been conducted to date, and many lack methodological rigor. Finkelhor (1994) analyzed reported prevalence rates in 21 countries and concluded that the prevalence of sexual abuse during childhood averaged around 20% for women and between 5% and 10% for men. More recently, Pereda et al. (2009) conducted a meta-analysis of prevalence studies in the field of sexual abuse, comprised of 65 original articles about child sexual abuse in 22 countries, and found significant difference in the prevalence of child sexual abuse by gender; the mean prevalence rate in men was 7.9% and in women was 19.7%. In addition, they noted that prevalence rates varied by continent, with rates highest in Africa and lowest in Europe. South Africa reported the highest prevalence rates for both men (60.9%) and women (43.7%), whereas France reported the lowest rates for both men (0.9%) and women (0.6%). Only three countries (i.e., Jordan, South Africa, and Tanzania) reported prevalence rates of child sexual abuse among men above 20%, whereas eight countries (i.e., Australia, Costa Rica, Israel, South Africa, Sweden, Switzerland, Tanzania, and the United States) reported prevalence rates of child sexual abuse among women above 20%.

Within the United States, sexual abuse of children is one of four major types of child maltreatment monitored through the National Child Abuse and Neglect Data System (NCANDS), an effort funded by federal government to collect and analyze data on child abuse and neglect from the states annually. In its most recent report, *Child Maltreatment 2011*, sexual abuse was the least common form of maltreatment, with less than 10% of children sexually abused. Of the 61 472 victims who suffered sexual abuse, 26.3% were 12–14 years of age and 21.8% were 15–17 years of age. Among the 885 003 perpetrators associated with maltreating a child, 6.2% (54 906) engaged in the sexual abuse of children. Further, 9 out of 10 of the perpetrators of child abuse and neglect were the child's parents, relatives, or the unmarried partners of the child's parents.

Additional information on sexual abuse of minors (those under 18 years of age) is available from the National Crime

Victimization Survey (NCVS), an annual self-report victimization survey in which persons aged 12 and older were drawn from a nationally representative sample of households in the United States. In 2011, an estimated 244 000 rape/sexual assault victimizations occurred, representing less than 4% of all criminal victimizations reported (Truman and Planty, 2012). Further analysis of NCVS data for a 15-year period reported that over 91% of all victims of rape or sexual assault were female. In comparing the sexual victimization rates across three time periods (1994–98, 1999–2004, 2005–10), the report concluded that rates of sexual victimization declined over time and by age group, with 12–17-year-olds reporting highest rate of sexual victimization (Planty et al., 2013). The rate of rape/sexual assault victimizations of youths aged 12–17 declined from 7.0 victimizations per 1000 youth in 1994 to 2.2 victimizations per 1000 youths in 2010 (White and Lauritsen, 2012).

Conducted between January and May 2008, the National Survey of Children's Exposure to Violence (NatSCEV) recorded the victimization experiences of a nationally representative sample of 4549 children aged 1 month to 17 years living in the contiguous United States and found that 1 in 16 (6.1%) of those surveyed were victimized sexually in the previous year and nearly 1 in 10 (9.8%) over their lifetimes. Sexual victimizations included attempted and completed rape, sexual assault by an adult or peer, sexual exposure (exhibitionism) by an adult or peer, and sexual harassment. Adolescents aged 14–17 were the most likely to be sexually victimized and girls were more likely than boys to be sexually victimized (Finkelhor et al., 2009b).

In addition to reports from surveys, additional information on sex crimes is available from the National Incident-Based Reporting System (NIBRS), an expansion of the Federal Bureau of Investigation's (FBI) Uniform Crime Reports (UCR). The UCR compiles information on crimes reported and arrests completed by law enforcement agencies throughout the United States. NIBRS collects a wider range of information on victims, offenders, and circumstances for a greater variety of criminal incidents than the UCR, however not every law enforcement jurisdiction reports data into NIBRS, so the data may not be representative of the United States. NIBRS provides information on sex crimes against children including sexual assault, statutory rape, child pornography, and prostitution. Finkelhor and colleagues have issued a series of reports on sex offending and victimization experiences of juveniles as reported in NIBRS. First, in an analysis of data collected for 2004 that included 29 participating states or more than 4 million criminal incidents, Finkelhor et al. (2009a) reported that juvenile sex offenders (those aged 6–17) numbered 89 000, comprised more than one-quarter of all sex offenders (juvenile and adult), and comprised more than one-third of sex offenders who victimized juveniles (those under 18). The vast majority (93%) of juvenile sex offenders were male and nearly half (46%) were between the ages 15 and 17. Compared to adults who committed sex offenses against minors, juvenile offenders were more likely to offend in groups, more likely to offend against acquaintances, more likely to victimize boys, more likely to victimize younger children (under age 12), and more likely to commit sodomy or fondling than rape. NIBRS data collected in 2000, that included 19 states or more than 2.8 million criminal incidents, indicated approximately 2900 incidents of child pornography were known to police. Nearly 6 in 10 victims were female, 1 in 4 were members of the offender's family, and 6 out of 10 victims were 12–17 year old (Finkelhor and Ormrod, 2004a). Additional information from NIBRS indicated that nearly 13 814 incidents involving prostitution were known to police in the 4-year period (1997–2000). Of these, about 5% of the incidents involved juvenile offenders, juvenile victims, or both juvenile victims and juvenile offenders. Compared to adult prostitution, juvenile prostitution incidents were more likely to involve male offenders, to involve a group rather than a single offender, and to occur in large cities (Finkelhor and Ormrod, 2004b). Finally, based on the analysis of data collected for NIBRS from 1996 to 2000, nearly 7557 persons aged 7–17 were victims of statutory rape. In more than 6 out of 10 of the statutory rape incidents, the victim and offender were acquaintances. Males accounted for approximately 5% of all statutory rape victims. In the vast majority of statutory rapes, victims and offenders were of the opposite sex (Troup-Leasure and Snyder, 2005).

Incest

Incest is commonly defined as "sexual relations between persons so closely related that their marriage would be illegal or forbidden by custom" (Flowers, 2006: 77). Finkelhor (1978) estimates that anywhere between 75% and 90% of all incest cases go unreported. Among reported cases of incest, the vast majority of aggressors are adult men and the victims are female children, typically between the ages of 6–11. Mother–son or mother–daughter incest is the least common type. Sibling sexual abuse is the least recognized form of incest and its prevalence is not well documented (Ballantine, 2012). However, it is estimated that the rate of sibling incest may be five times the rate of parent–child sexual abuse (Finkelhor, 1980). In most sibling incest, the aggressor is an older male child and the victim is a younger female child.

Pedophilia

Pedophilia is a term often used interchangeably with child sexual abuse or child molestation. However, pedophilia is a clinical diagnosis referring to a sexual preference for children over adults that often includes fantasies, and may not result in actual contact with a child (i.e., noncontact sexual abuse). The Diagnostic and Statistical Manual (DSM-V) used to guide clinicians modified the diagnosis of pedophilic disorders to include three types: the pedophilic type (attracted to prepubescent children, generally younger than 11), the hebephilic type (attracted to pubescent children, usually ages 11 through 14), and the pedohebephilic type (attracted to both) (Harvard Medical School, 2010). Pedophiles are either severely distressed by these sexual urges, experience interpersonal difficulties because of them, or act on them. In general, most individuals who engage in pedophilia are male; the ratio is estimated to be 10 males to every one female (Cohen and Galynker, 2009). However, there is growing interest in female sex offenders (Hall and Hall, 2007). Most of the studies on pedophilia have involved men convicted of crimes against children, and as such may not represent the population of persons with pedophilic tendencies (Harvard Medical School, 2010). Many typologies or classifications of pedophiles have

been developed, including whether they are attracted to a particular age range and/or sex of child, whether they target only family members, and whether child pornography and/or a computer was used to engage the child in sexual activity (Hall and Hall, 2007). Researchers have noted many misconceptions surround child sex offenders including that all are pedophiles, that they target strangers, that all were victims of child sexual abuse themselves, that all have high rates of recidivism (Richards, 2011).

Child Sex Trafficking/Commercial Sexual Exploitation of Children/Minors

Child sex trafficking has become an important topic of both domestic and international interest. While variously defined, child sex trafficking, also referred to as the commercial sexual exploitation of children or minors (CSEC/CSEM), includes at its core sexual abuse of a child by another person who receives money for providing another person sexual access to that child. The child may be engaged in prostitution, nude dancing, stripping, pornographic film/images, or other forms of transactional or fantasy sex (Flowers, 2001). By most estimates, child pornography is a multibillion dollar global enterprise with the United States not only generating the biggest demand (yielding an estimated $6 billion annually), but also producing 85% of the world's supply (Flowers, 2001). According to the United Nations, the United States ranks second in the world (behind Italy) as a destination or market for sexual exploitation for both children and adults (Monzini, 2004). Annual estimates on the scope of sexual exploitation of children in the United States range from as few as 14 500–17 500 (Markon, 2007) to as many as 300 000–500 000 (Estes and Weiner, 2001). However, reliable information on the nature and extent of child sex trafficking in the United States is scarce (Finkelhor and Ormrod, 2004a,b). The UCR, NIBRS, and NCVS do not provide a national statistical picture of the extent of child sex trafficking (Finkelhor and Ormrod, 2000). A recent report by the National Institute of Justice (NIJ) stated that the number of known cases is growing; between 1998 and 2004 almost 300 000 calls made to the National Center for Missing and Exploited Children's CyberTipline reported CSEC (Albanese, 2007). CSEM is a complex problem that primarily occurs in large urban areas in the United States (Finkelhor and Ormrod, 2004a), and affects almost equally male and female teens (Curtis et al., 2008; Finkelhor and Ormrod, 2004a). Runaways and vulnerable youths with a history of physical or sexual abuse also are targets of sexual exploitation (Wolak et al., 2008).

Sex Crimes against Adults

Adults, unlike children, rely primarily on the criminal justice system to respond to reports of sexual victimization, thus information on the extent of adult victimization and offending is available from sources discussed previously (NCVS, UCR, and NIBRS). Data analyzed from the NCVS has noted that between 1994 and 2010 the rates of sexual victimization have declined over time for all age groups (Planty et al., 2013). In 2010, about 270 000 rape or sexual victimizations (a rate of 1.8 per 1000 females) occurred. In 9 out of 10 incidents: the victim was a female, a single offender was involved, and no weapon was used. Only 35% of rape/sexual assaults were reported to the police in 2010.

The UCR collects information on attempted and completed acts of forcible rape, defined as the carnal knowledge of a female forcibly and against her will. This definition excludes male victims and victims who are under the age of consent to engage in sex. The UCR broadened its definition of forcible rape in 2011 to include vaginal or anal penetration with any body part or object, or oral penetration by a sex organ of another person, without the consent of the victim. UCR data reported after January 2013 will reflect this definition. Estimated rates of rape are not broken down by age of victim. For 2011, the estimated number of forcible rapes was 83 425 and the rate of forcible rapes was 52.7 per 100 000 persons (UCR, 2012). For 2011, 19 491 arrests for forcible rape were reported. The UCR figures are significantly lower than those reported in the NCVS. Sexual assault continues to be one of the most underreported crimes, so the UCR figures are not a valid estimate of its true extent, as evident by the higher number reflected in the NCVS.

The UCR also provides information on prostitution incidents involving adults, and in 2013 will report information on incidents of human trafficking, including sex trafficking. Both prostitution and sex trafficking involve the sale of sex for money (e.g., commercial sex). However, the key distinction is that in sex trafficking, force, fraud, or coercion is used to compel a person to engage in the sale of sex for money and in prostitution such elements are not present. The U.S. Department of State (2005) estimates 600 000–800 000 persons are trafficked for sex and labor annually across international borders worldwide; recent estimates suggest that 14 500–17 500 individuals are trafficked annually into the United States (U.S. Department of State, 2006). It is believed that the majority are trafficked for sex. The Uniform Crime Report indicated that law enforcement agencies made 62 670 arrests for prostitution in 2010; two-thirds of those arrests were of women (Snyder, 2012).

The Centers for Disease Control (2011) published results of a nationally representative survey of adults aged 18 or older in the United States on both lifetime and annual prevalence rates of their experiences with sexual violence victimizations. The National Intimate Partner and Sexual Violence Survey (NISVS) found that 1%, or approximately 1.3 million women, reported being raped by any perpetrator in the 12 months prior to taking the survey. Nearly 1 in 5 women (18.3%) and 1 in 71 men (1.4%) in the United States had been raped in their lifetime. More than half of female victims of rape reported that the perpetrator was an intimate partner and more than half of male victims reported being raped by an acquaintance. The majority of both female and male victims reported experiencing violence from one perpetrator and that perpetrator was most likely male.

Explanations of Sex Offending

The medical model has dominated the American perspective on what causes sex offending and how best to treat it (Zilney and Zilney, 2009). There is no one single cause of sex offending. In today's society, when thinking of what motivates sexual offending, one usually thinks that it is motivated by the need

for men to have power and control over the victim. However, when one examines the range of sex crimes that are committed, especially when the victim or perpetrator is a minor, and as the age difference grows between the victim and perpetrator, other explanations may be needed. Research on typologies or subtypes of sex offenders began by differentiating between offenders who targeted children versus adults, with further refinements thereafter. In addition, the typologies of child sex abusers and rapists that have developed over the years often sought to identify the motive for sex offending, as doing so was seen as critical to effective intervention. Explanations for sex offending against children are dominated by individual-level explanations that attempt to identify a pathological factor, such as increased sex drive or aggression; the presence of deviant sexual arousal, interests, or preferences; and deficits in intimacy or possession of dismissive attachment styles.

Similarly, research of men convicted of rape argued that sexually aggressive men differed from other men in antisocial tendencies, nonconformity, impulsivity, and hypermasculinity, but such differences faded when comparison was made to admitted rapists who were not convicted (Meyer, 2000). Feminist theorists argue that sexual violence is caused by the social structure. Specifically, patriarchal society posits that men are both structurally and ideologically superior to women. Women in patriarchal cultures are socialized to be submissive and inferior to men, who are entitled to access and regulate of women's sexuality (Zilney and Zilney, 2009). A major tenet of feminist's conceptualization of rape is that it is a violent act motivated by power and anger and not by sexual desire.

Finally, prostitution and sex trafficking are viewed largely as crimes motivated by economics (Kara, 2009; Wheaton et al., 2010), with rational choice theory applied to the crime of trafficking. Rational choice theory posits that individuals will engage in rational choice in the marketplace, and compare costs and benefits in the market in order to obtain the highest profit or level of well-being. In the context of sex trafficking, sellers (traffickers/pimps/managers) offer buyers (employers/johns/customers) differentiated products (vulnerable individuals/prostitutes/sex workers) based on price and preference. Economic profit is the driving motive for sex trafficking. Powerless and marginalized populations (in which women and children are disproportionately represented) are primarily targeted for economic exploitation.

Emerging Issues in Sex Crimes

Female Sex Offenders

Sex offending by women was originally been believed to be a rare event; however, females are involved in upward of 5% of sex offending (Bunting, 2007). Further, incidents of female sex offending are believed to be underreported because victims are embarrassed and/or fear that their disclosures will be dismissed as fabrications due to cultural assumptions about femininity and the glorification of sexual activity between adult women and underage men (Oliver, 2007). Female sex offenders often use strategies to subdue their victims and take advantage of victims with either physical force, methods of exploitation, or verbal abuse (Fisher and Pina, 2013). Female sex offenders, compared to male sex offenders, typically target family members and often engage in offending with a male co-offender (Oliver, 2007). Female sex offenders are less likely to repeat their offending behavior and as a result, are treated more leniently by the courts as they are seen as less of a threat (Sandler and Freeman, 2011).

Juvenile Sex Offenders

A significant minority of child sexual abuse (20–50%) is committed by adolescents not adults (Veneziano and Veneziano, 2002). While research on this population is growing, far less is known about juvenile sex offenders than their adult counterparts. Juvenile sex offenders vary in terms of the age of onset of offending and the age of the victims targeted for sexual abuse. Generally speaking, adolescent sex offenders target those younger in age, females, and persons that they know. Juvenile sex offending is often linked with conduct disorder, antisocial behavior, or substance abuse (Gerardin and Thibaut, 2004). According to Gerardin and Thibaut (2004), juvenile sex offenders were often victims of sexual or physical abuse; studies report prevalence of prior abuse among juvenile sex offenders to range from 40% (Ryan et al., 1996) to 80% (Friedrich and Luecke, 1988; Ryan et al., 1987). Additional research has examined if juveniles who engage in sex offending are likely to continue in that pattern of criminal activity into adulthood. Zimring et al. (2007) in their longitudinal study found no evidence that juvenile sex offenders specialize in sex offending as adults, and that the best predictor of adult sex offending was frequency of police contact and not sex offending as an adolescent.

Sexual Assaults in Institutional Settings

The Military

The official definition of sexual assault in the armed forces includes "intentional sexual contact, characterized by use of force, physical threat or abuse of authority or when the victim does not or cannot consent (Army Regulation 600-20, as cited in Hillman, 2009)." Attention to the issues of sexual violence in the military occurred during the Vietnam War and gained momentum after the publication of Susan Brownmiller's groundbreaking book, *Against Our Will* in 1975. Recent research suggests that military-on-military sexual violence is a significant part of military crime and it persists across lines of rank and branches of the service (Hillman, 2009).

Information on the extent and nature of sexual violence in the military comes in two forms: actual reports filed to command and estimates based on anonymous claims. Military services received 3374 reports of sexual assaults during federal fiscal 2012 (1 October 2011 to 30 September 2012), and 26 000 persons made an anonymous claim of sexual assault but chose not to report the incident U.S. Department of Defense (2013). Estimates based on 2010 reports indicate that males comprised about 55% of sexual assault victims. Survivors may be reluctant to report and perpetrators may be improperly disciplined due to a military climate often described as supportive of victim-blaming, lacking in accountability, and misogynistic.

College Campuses

Given the average age of traditional college students (18–24) coincides with the age of active criminal offending, coupled with a lack of supervision/guardianship and increased

exposure to consumption of alcohol and illicit drugs, rape/sexual assault is an identified issue that many colleges are required to address. Originally passed in 1990, the *Jeanne Clery Disclosure of Campus Security Policy and Campus Crime Statistics Act* is a federal law requiring colleges and universities across the United States to disclose information about crime on and around their campuses. The U.S. Department of Education hosts a Web site that allows the public to retrieve information on the incidents of crime reported to police for single colleges or group of colleges. The Clery Act has been amended several times (1992, 1998, 2000, and 2008). Most recently in the reauthorization of the Violence Against Women Act, the Campus Sexual Violence Elimination Act (Campus SaVE) was approved, which amends the Jeanne Clery Act and affords additional rights to campus victims of sexual violence, dating violence, domestic violence, and stalking.

Similar to reports of sexual assault in the broader community, the number of sexual offenses reflected in official reports to undercount its true occurrence. There were fewer than 500 forcible sexual offenses reported on college campuses in the United States in 2011 (UCR, 2012); the estimated number of women enrolled in college in fall 2011 was over 5 million. The NIJ has sponsored three separate surveys to measure the nature and extent of sexual assaults on college campuses (Fisher et al., 2000; Krebs et al., 2007, 2011). The rates of sexual assault varied somewhat across the studies due to the different time frames and populations studied (first-year college freshmen, all students enrolled, historically black colleges and universities). Overall, findings indicated that slightly fewer than 20% of women reported experiencing a completed or attempted sexual assault since entering college, and nearly 5% reported experiencing a forcible sexual assault since entering college.

Correctional Institutions: Adult Prisons/Jails and Juvenile Facilities

The *Prison Rape Elimination Act* (PREA) was federal legislation passed in 2003 in an attempt to combat the growing problem of rape and sexual assault in prisons and jails across the United States. PREA applies to all correctional facilities, including prisons, jails, juvenile facilities, military and Indian country facilities, and Immigration and Customs Enforcement (ICE) facilities. The act established guidelines to prevent rape in custodial confinement. The Bureau of Justice Statistics is required to conduct a comprehensive statistical review and analysis of incidents and effects of prison rape (National PREA Resource Center, 2013).

The Bureau of Justice Statistics (Beck et al., 2013a,b) in a series of reports produced annually provides summaries of the incidents of prison rape reported in more than 7600 adult correctional facilities. For fiscal year ending 30 June 2012, data indicated that 4.0% of state and federal inmates reported one or more incidents of sexual victimization by another inmate or facility staff; about 2.0% (estimated 29 300) state and federal prisoners reported an incident involving another inmate. Among jail inmates, 3.2% of inmates reported one or more incidents of sexual victimization by another inmate or facility staff; about 1.6% of jail inmates (estimated 11 900) reported an incident with another inmate. Rates of victimization were higher among inmates who identified as nonheterosexual. Information on the victimization experiences of juveniles held in adult prisons and jails were included. Nearly 1.8% of juveniles aged 16–17 held in adult prisons and jails reported being victimized by another adult, and 3.2% of juveniles aged 16–17 held in adult prisons and jails reported being victim of sexual misconduct by facility staff.

The Bureau of Justice Statistics reported on the 2011–12 incidents of prison rape that occurred in over 300 juvenile facilities in the United States. Findings indicate that 9.5% of adjudicated youth in custody reported one or more incidents of sexual victimization by another youth or staff. The vast majority (8 out of 10) victims reported more than one incident. The majority of victims reported an incident involving staff, notably female staff. Juvenile victims reported that in about one-third of the cases, facility staff initiated sexual contact but closer to half of the time the victim reported initiating sexual contact. The different methods used to encourage youth participation in sexual contacts included the threat of force, offer of protection, and the promise of drugs and alcohol. Similar to adults victimized in custody, youths who identified themselves as being nonheterosexual had higher rates of victimization.

Conclusion

A significant number of people are victims of sex crimes in their lifetime and current estimates of the prevalence and incidents of such criminal victimization do not accurately reflect how widespread this problem is. It appears from available information that the victims of sex crimes are predominantly female, the perpetrators are predominately male, and the victims and perpetrators are known to each other. There is no single cause of sex offending and explanations vary from focusing on the individual-level pathology of offenders to societal-level explanations noting patriarchal social structure. While adult men are considered the primary perpetrators of sex crimes, recent research has noted that women are involved in a minority of sex offending (often as co-offenders with men and typically when the victim is a family member) and that adolescents commit a significant amount of sex crimes against their peers or younger children. Sexual victimization of persons in the armed forces, on college campuses, and in correctional facilities has been the focus of much attention and legislation has been enacted to prevent and enhance responses to such sexual victimization.

Sex Life Challenges: The Finnish Case

Osmo Kontula, Population Research Institute, Family Federation of Finland, Helsinki, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In international comparison, Finland is a country where social well-being and gender equality are exemplarily progressed. One could assume that this had caused positive impact also on sexual well-being. This assumption was tested by utilizing nationally representative sex surveys that have been conducted in Finland during several decades. The results are challenging after there was found increasing lack of female sexual desire, decreasing frequency of sexual intercourse, and unwanted trends in female orgasms. Some explanations for these unexpected results were given.

Introduction

Finland is one of the few countries where there is available nationally representative surveys of sexual activities and values among the adult population. According to many international indicators, social progress is well advanced in Finland. In relation to social well-being, the European Quality of Life Survey gave the highest rates in happiness in Europe for Finland and Denmark. This has some implications for sexual values and activities. Sexual images and values are evolving into a more positive and more liberal approach.

Women have a unique position in Finland in international comparison. The rate of women working full time is in Finland, the highest in Western Europe – partly thanks to extensive public childcare that is a subjective right for everybody. Based on the Gender Equity Index, introduced by Social Watch, Finland is number one in gender equity in the world together with Sweden. In education, the results of the Program for International Students Assessment (PISA) evaluation (60 countries), OECD, Finland has been several times number one in the world. Women outnumber men in higher education and comprehensive sex education is at the top level in Europe (Kontula, 2010). This social and educational progress has created positive circumstances for sexual activities also among aging population (Kontula and Haavio-Mannila, 2009; Kontula, 2013).

During the last decades, there was a major progress also in sexuality issues in Finland. Two nationally representative surveys of the sexual behavior and sexual attitudes in 1971 and 1992 showed that people's attitudes had become more liberal, sexual behavior more equal, women sexually more active, and that especially women's sexual satisfaction had increased during the 20 years between these two surveys. The increasingly more copious, open, and versatile treatment of sexuality in the different media was estimated to have been one of the causes of this positive change (Kontula and Haavio-Mannila, 1995; Kontula and Kosonen, 1996).

Public discourse defines acceptable forms of sexuality and delivers disapproval for 'unacceptable' forms, as well as for deeds that have been deemed illegal. In the West, an individual's right to sexual self-determination now represents an important sexual standard, as long as it does not conflict with someone else's right to sexual self-determination. In our culture, sexual interaction occurs as the outcome of a negotiation between two individuals; society is generally unwilling to interfere with these mutual understandings and agreements. The lines are mostly drawn on a 'just-in-case' basis, not because there is any persuasive evidence of the postulated harms (Kontula, 2009).

Over the past 20 years, the key shift in sexual culture in the West has been the opening up of the private sexual sphere into something that is now part of the public sphere. This is manifested in the public proliferation of images of scantily clad people, intimate stories about well-known personalities, and new technological breakthroughs in pornography (private webcams, annual sex expos, and so on). Sex and nudity are a natural and everyday part of our public culture. At the same time, marriage and cohabitation have lost their power to determine whether a particular sexual relationship is acceptable or not. Sex is for everyone, even though not everyone has an equal opportunity to engage in it.

In many respects sexual trends in Finland before the 2000s correspond with research data compiled previously in Europe on the same topic (Sandfort et al., 1998). The broader shift that has occurred in the West has meant a greater number of sexual partners before forming a committed relationship, lower level of commitment in relationships, increases in masturbation, lifetime partners and parallel relationships, more frequent intercourse, increasing commonness of oral and anal sex, and increased condom use. Finland has deviated from the European trends only in that neither intercourse frequency nor condom use increased simultaneously.

The aim of this article is to present the greatest present-day challenges in sexual life in Finland based on the results of the latest national sex surveys. These challenges are increasing lack of female sexual desire, decreasing frequency of sexual intercourse, and unwanted trends in female orgasms.

Method

The FINSEX study (Kontula, 2009) has tracked Finnish sexual trends since the 1970s up to the present. Some survey questions that map out sexual behavior in youth yield data all the way from the 1940s, a wealth of knowledge that is unique even worldwide.

Four national sex surveys were conducted in Finland in 1971, 1992, 1999, and 2007. Each survey's sample was drawn from the Central Population Register, so that all Finns had an

equal opportunity to be selected into the sample. In these four population surveys, respondents aged 18–54 in 1971 and 18–74 in 1992, 1999, and 2007 were selected. Numbers of respondents were 2152 (1971), 2250 (1992), 1496 (1999), and 2590 (2007).

Response rates were 91% (1971), 76% (1992), 46% (1999), and 43% (2007). The higher response rates in 1971 and 1992 were due to face-to-face interviews at respondents' homes. In 1999 and 2007 the data collection was carried out by Statistics Finland as a mailed survey (because of lower costs), which caused lower response rates.

The impact of lower response rates in the 1999 and 2007 studies on comparability with the 1971 and 1992 surveys has been evaluated particularly by analyzing the ways in which people in a particular birth cohort have responded to the same questions concerning their own youth. The representativeness and comparability of the data in relation to 1992 data remained quite good, except in the case of male respondents over the age of 55. The 1999 and 2007 findings (mailed surveys) provide a slight underestimation of men above the age of 55 (sexual initiation somewhat later, and sexually a bit more monogamous in their life time), compared with the entire age group of the respondents.

More detailed information on the sampling, interviewing, and questionnaires is available in Kontula and Haavio-Mannila (1995), Haavio-Mannila et al. (2001), Haavio-Mannila and Kontula (2003), and Kontula (2009).

Results

Gender Differences in Sexual Desire and Increasing Lack of Female Sexual Desire

The first challenge in sex life in Finland is the major gender difference in sexual desire and increasing numbers in lack of female sexual desire. Compared with Baumeister et al.'s (2004) list of indicators of sexual desire, this study utilized respondents' own assessments regarding sexual desire, preferred frequency of sex, and lack of sexual desire.

In 2007, for the first time, Finns were asked to evaluate their own sexual desire in response to the following question: "How often do you experience sexual desire?" The most typical response among both men and women was that they experienced sexual desire several times a week. In terms of frequency, this amounted to 14 times per month. On average, men experienced sexual desire much more frequently than women, on average 21 times per month (medium value 12), whereas women experienced it on average 9 times per month (medium value 4). Young people, compared with older people, were much more likely to feel desire – men, on average, every day, and women, a few times a week. Nearly one in three young men, but only 5% of young women reported feeling sexual desire more than once a day (Figure 1).

Compared with young and middle-aged women, men in the same age groups experienced sexual desire twice as frequently. For men in the older age group, sexual desire was four times as frequent as for women. These gender differences in sexual desire are supported by earlier international research (Baumeister et al., 2004).

An interesting observation in terms of male and female sexual desire is that the level of desire reported by men is compatible with the level of desire in women approximately 20 years younger, and vice versa. This may explain relationships where an older man has found a much younger spouse. If sex and desire are important in this type of couple formation, the choice may not only be appealing on the basis of feelings, but also on the basis of rational reasoning.

In this way, a young woman may get herself a partner whose sexual desire does not significantly exceed her own. Based on these averages, it would be much more difficult for an aging woman to find a young man whose sexual desires are well suited to her own.

This experience gap between the sexes was also visible in responses to a question about whether or not respondents were satisfied with the frequency of intercourse in their current relationship. Approximately 60% of middle-aged women were satisfied with the frequency of sex in their relationship, but only one-third of men of the same age felt similarly. Two-thirds of men and one-third of women would have liked more frequent intercourse. In other words, middle-aged women had been much more successful than men in satisfying their need for sexual intercourse.

Figure 1 Feels sexual desire at least a few times a week.

The desire for intercourse between married women and men differed to a substantial extent only in relationships that had lasted more than 10 years. In long-term relationships, men were much more likely than women to desire sexual intercourse more frequently. On the other hand, the proportion of men wanting more frequent intercourse was highest in relationships that had lasted slightly more or less than 10 years, and highest among women in relationships that had lasted slightly less than 10 years. To the extent that sexual dissatisfaction is an important factor in explaining marital infidelity, this stage of marriage is a particularly critical period.

In 1992, 1999, and 2007, the FINSEX survey included a question asking respondents whether they had had a problem with lack of sexual desire in themselves or in a partner within the last year. Lack of desire was defined here as a problem, if a respondent reported that the issue arose at least fairly frequently, either in the case of the respondent him or herself or in the partner. The introduction to the question specifically addressed the incidence of various sexual problems (Figures 2 and 3).

Lack of own sexual desire was significantly more common among women than men. In 2007, 41% of women and 12% of men had experienced lack of sexual desire at least fairly frequently. The reported prevalence of lack of desire increased among men and women between 1992 and 2007, but only among women did the trend continue also from 1999 until 2007. As a result, the desire gap between women and men has grown even more.

In a number of international studies, the proportion of people who have no interest in intercourse has fluctuated between 10 and 15%. In the present study as well, 14% of women reported experiencing lack of sexual desire very frequently.

Men reported a partner's lack of sexual desire significantly less frequently than women themselves reported feeling lack of desire. It seems quite likely that men were not always fully aware of the lack of desire on the part of their partners, who had been able to conceal it from them. In this way, women were protecting their own sexual image in the eyes of a male partner and had avoided hurting his feelings with repeated complaints about not feeling desirous.

The Declining Frequency of Intercourse

Second challenge in sex life in Finland is a declining frequency of sexual intercourse. Of all men, 61% and of all women, 53% had had sex within the last week. The gender difference here stems from the greater number of aging female widows who no

Figure 2 Lack of own sexual desire somewhat frequently in relationship during the last year, women.

Figure 3 Lack of own sexual desire somewhat frequently in relationship during the last year, men.

longer had the opportunity or desire for a sexual relationship. Compared with figures from 1999, the numbers had declined by several percentage points, and compared with the early 1990s and 1970s, the decline was about 10 percentage points. In other words, fewer Finnish people reported that they had had sex within the last week.

Sixty-six percent of young men and 62% of young women had had sex during the last week. Among middle-aged respondents the proportions were 65 and 60%, respectively, and among the oldest age group 53 and 35%, respectively. Thus, with the exception of the oldest group, approximately two in three Finnish people had had sex at least once the week before. The numbers for middle-aged respondents had fallen by nearly 10% from the 1999 results and approximately 15% from 1992. The decline of sexual intercourse was rather significant among middle-aged respondents.

When the frequency of intercourse reported by Finns is converted into numbers, it turns out that the average man was having sexual intercourse 4.8 times per month, the average woman 4.3 times per month. When also taking into account the median frequency of sexual intercourse, it is further revealed that half of all men and women had sexual intercourse at most once every 2 weeks. Based on this, Finnish people do not have very active sex lives (Figures 4 and 5).

The changes in frequency of sexual intercourse over the 8 years are thought provoking. In 2007, both men and women were having less sexual intercourse by an average of once per month than in 1999. Put another way, the frequency of sexual intercourse among Finns had declined by approximately 20%. Frequencies were down for young and middle-aged people compared with all previous years. Only among the oldest age group did the frequency rise from 1992 (no data is available for 1971), but even those levels declined again after 1999.

The frequency of intercourse declined in all relationship types. In 2007, married men were having sexual intercourse 4.6 and women 4.3 times per month. This amounts to a decrease of one session of intercourse per month. Cohabiting respondents were having sexual intercourse approximately six times per month, a veritable crash from previous figures; a 25% drop, translated to two events of sexual intercourse. Living-together relationships had the highest frequency of intercourse, more than seven times per month, or nearly twice per week. Even this figure had declined by one. The frequency among single people was very irregular and averaged less than

Figure 4 Number of intercourse in month, women.

Figure 5 Number of intercourse in month, men.

once a month. Even that represents a slight drop. The decrease in intercourse frequency has affected every category of relationship in Finland.

A whole year or more had passed since the last time that 10% of men and 14% of women had had sex. Among the oldest age group, the figures were 17 and 32%, respectively. These people were usually single-dwellers or single, of whom two-thirds of men and half of women had been without sexual intercourse for more than 1 year. At the same time, there were also marriages where factors like illness or injury had caused the cessation of sex. Of married men and women, 8% had had no sex in the last year.

Sexual Pleasure and Decreasing Frequency of Orgasms

A third challenge in sex life in Finland are declining trends in sexual satisfaction and orgasms. Ninety-four percent of men reported having an orgasm always or almost every time they had intercourse, and one in two reported having an orgasm every single time. Only 5% of men had difficulty having orgasms. A few percent rarely experienced an orgasm when having intercourse. Orgasms are not a given even to all men.

For women, having an orgasm from intercourse was much less guaranteed than for men. Forty-six percent of women said that they always or nearly always had an orgasm when having intercourse, but only 6% always had one. Nearly one-fifth of women had an orgasm approximately half of the time and about one-third had one fairly infrequently at most.

Based on the study's findings orgasticity was unfortunately headed in a worse direction over the 8 years following 1999. This applies to the responses of both men and women, young and middle aged (Figure 6).

In 2007, 9% of women reported never having had an orgasm from intercourse. Difficulties experiencing orgasms affect a large proportion of women. In the earlier studies, the proportion of women who had never experienced an orgasm from sexual intercourse was 5%, lower than in 2007.

There is much to think about and wonder in only 42% of young women (53% still in 1999) reporting that they usually had an orgasm during intercourse, whereas 40% said that they had them fairly infrequently at most.

According to the 2007 findings, 13% of young women had never had an orgasm from intercourse. Fifty-one percent of middle-aged women usually had an orgasm during intercourse (60% in 1999). One-third of middle-aged women and slightly more than one-third of older women had an orgasm fairly infrequently at most. Difficulties having an orgasm among middle-aged women had become as common as it had been in the early 1970s, after a period of temporary improvement. The situation among young women was clearly even worse than it had been in the early 1970s.

The proportion of people who had an orgasm the last time they had intercourse was close to the proportion of those who said that they generally had an orgasm from intercourse. Of men, 92% and of women, 55% had an orgasm the last time they had intercourse. It speaks to the confusion surrounding the concept of 'orgasm' that nearly one in ten women was not able to say whether or not she had had an orgasm the last time she had intercourse.

The findings indicate that women differ from one another greatly in terms of their tendency or capacity to experience orgasms. A significant portion of women experienced persistent problems having orgasms from intercourse, whereas many (12%) found it easy to have multiple orgasms. The inequality in sexual enjoyment among women was drastically greater than among men. It is intriguing why women are experiencing greater, not fewer, problems with orgasms, even though the opportunities for sexual enjoyment now seem better than ever.

Discussion of Sexual Challenges in Finland

It is a great challenge to try to explain why in Finland, where gender equality and social welfare are highly progressed in international comparison, the lack of sexual desire is increasing, frequencies of sexual intercourse are decreasing especially in the middle age, and difficulties to experience orgasm in sexual intercourse are increasing. It was assumed that sexual well-being should improve along the progress of other social well-being.

Sexual desire is a key factor distinguishing men from women in sexuality issues. According to a number of measures,

Figure 6 Orgasm during sexual intercourse almost always or usually women.

male sexual desire is manifested at least twice as often as female desire, and men would like to have sex twice as often as women. In every age group, the frequency of sexual intercourse that would have sufficed to satisfy male respondents was higher than for female respondents. An additional dimension comes from the repeated lack of sexual desire reported much more frequently by women than men. On the basis of available data it is not possible to make the claim that the gap between male and female desire would be shrinking in Finland since the 1970s. All of these factors have naturally had practical consequences for sexual interaction between men and women. Need for negotiations and different compromises in love making are increasing.

The findings reveal that women were able to fulfill their desires for sexual intercourse more successfully than men, having the frequency of sex in the relationship that they wanted. This suggests that women were more frequently gatekeepers and thus better able to decide when and how often the couple had sex. This role model continues to persist in Finnish relationships.

A particular challenge lies in solving the problem of the significant increase in women's loss of sexual desire. It is not a case of decreasing desire in long-term relationships, of becoming fed up and bored. The issue of libido loss had also expanded to the relationships of young adults as well as new relationships.

There is an intriguing association behind loss of sexual desire. When the incidence of lack of desire was analyzed in the different surveys by actual frequency of sexual intercourse, it seems that lack of desire did not vary by frequency category. What does this mean? It means that if the actual frequency of sexual intercourse reported by women had not dropped so much in recent years, the incidence of lack of desire among women apparently would not have been any greater than previously. Lack of intercourse decreases the desire to have intercourse. This suggests that female sexuality is much like an unused machine – it must first be oiled before it is functional again.

The motivation to have sex was not affected by any deterioration in the quality of intercourse, except on the part of orgasms, and did not cause people to invest less in intercourse. In 2007, the same proportion of women as in earlier surveys had found their latest sexual intercourse very enjoyable, and the proportion of men who did had actually grown.

Why do men have higher sexual desire than women? One explanation could be based on the social exchange theory (Sprecher, 1998). Within this theoretical framework one could think that the greater rewards that men achieve from sexual interaction could explain their stronger sexual desires. This might make sense in that men experience orgasms so much more often and easily in intercourse compared with women. In other words, men might be more motivated to seek intercourse as something that offers them particular rewards. This viewpoint is supported also by the finding that women who enjoyed sexual intercourse, and got more pleasure out of their sex lives than other women, were also less likely to experience lack of sexual desire.

This theory of 'pursuing rewards' still does not explain the differences between men and women in a comprehensive way, because even women who always had orgasms during intercourse desired to have sex somewhat less frequently than similar men. This perspective nevertheless opens up the possibility of matching male and female desire to suit one another better. If women were to enjoy intercourse more and have orgasms more regularly, the desire gap between the genders should decline.

A surprising and thought-provoking finding and challenge in the study is the decline in intercourse frequency in the 2000s. For example, from 8 years before, there was a 10–15% drop in respondents of all ages who reported that they had had sex within the last week. Only 45% of men and 40% of women had had sexual intercourse in the last week. In terms of frequency figures, Finnish respondents had lost one session of sexual intercourse per month, or 20%, compared with figures 8 years prior. Also compared to the early 1970s, people were having less sex now. Frequency of sexual intercourse declined most in the age group of 25–40-year-olds. The frequency had remained the same for people aged over 50. What could explain the change?

The decline in intercourse frequency that has taken place in Finland is not entirely unique. For example, researchers in the United States and Germany found already in the 1990s that when measured by intercourse frequency, people were not very sexually active. The finding conflicts with the media images that depict passionate, tempestuous sex lives, and the worry about the over-sexualization of our lives. The sex lives of most real people are somewhat modest.

The most typical wish expressed by Finnish respondents was to have sexual intercourse twice a week. People who had achieved this rate were also generally happy with the amount of sex they were having. Most respondents came up short, having only half the sex they would have liked. For this reason, more and more Finns expressed dissatisfaction with their sex life as a whole. Quality was no substitute for quantity in this case. The study's results do not support the claim that the frequency of sexual intercourse is not important from the standpoint of sexual happiness. Certainly, there will be individual exceptions to this.

When measured through the frequency at which Finns had intercourse, their sex lives seemed on their way to growing passivity. The picture looked different when using another measure of sexual activity on a par with sexual intercourse – masturbation. When looking at how many men and women of various ages had been sexually active (sexual intercourse and/or masturbation) within the last week, it turned out that, in 2007, Finnish men and women were approximately as sexually active as they had been according to the two previous surveys conducted in the 1990s. Compared with middle-aged respondents in the 1970s, people were clearly even more sexually active. Further, respondents aged 55–74 years proved to be more sexually active in the last two surveys, compared with the early 1990s.

One of the study's key findings was that sexual activity among Finnish people was shifting to a significant degree from sexual intercourse to masturbation, also among couples. Naturally, this invites questions as to why it has happened. At least in those relationships where both partners are busy with work, possibly on different work schedules, this may be the case. In part, though, masturbation serves to compensate for the decrease in intercourse. The scope is not very broad, based

on the finding that masturbation was already increasing fast at the time when the frequency of intercourse in relationships had not yet significantly changed.

There are those who see the proliferation of masturbation as a sign of sexual emancipation. Masturbation is autonomous sex and does not require a demanding level of interaction with a partner. It's easy and presents no performance anxiety. Masturbation is suited to busy lifestyles and a culture of interaction that demands ever higher levels of sexual performance. As sexual gratification is nevertheless becoming increasingly important to people, the role of masturbation inevitably grows, as indicated by the findings of this study.

Slowly, people have begun to emancipate themselves from their feelings-based relationships, moving from shared sex toward a more individualistic experience of sexual pleasure – masturbation or self-pleasuring. Masturbation has its own justification, and it is increasingly practiced alongside established relationships. With its help, some people are able to escape the high demands imposed by our modern sexual etiquette, with its joint negotiations and situational considerations of the appropriateness of taking sexual initiative. For these people, masturbation is not a substitute for too little sex, but a different and easier form of sexual pleasure. To some extent, this is also a manifestation of a partial distancing between sex and love.

Social and public discourse on the subjects of gender and sexuality have for some time underscored women's right to sexual enjoyment. This enjoyment is often linked to the positive context of a couple relationship and the promotion of sexual well-being. At the same time, public discourse loads additional expectations on men to offer their female partners proper sexual fulfillment. Men's obligation to please their spouse is already paralleled by their earlier obligation to bear responsibility for the family's livelihood.

The great mystery of Finnish sexuality is why difficulty having orgasms has increased in the twenty-first century, at a time when information about how to better achieve orgasms proliferates. Women's and health magazines are full of instructions for the pursuit and cultivation of sexual pleasure and sexuality education has improved substantially. Women's sexual rights have been acknowledged already for a long time.

The proportion of young and middle-aged women who had orgasms through sexual intercourse nearly always or most of the time had fallen by 10 percentage points, and even among men, the proportion of men who always reach orgasm through intercourse had dropped by 15%. There was up to a 20% drop in cohabiting women who had orgasms through intercourse most of the time. In young women, this was associated with the clearly increasing difficulties of having orgasms in the first years of a relationship. Hence, fewer young women considered their sexual relations 'highly enjoyable.'

Women's responses indicated that they experienced more orgasms when they felt that the sex was initiated together with the partner. This may represent one key reason for why women are finding it more difficult to have orgasms. Among young women in particular, more and more felt that the latest sexual intercourse had not been initiated together, but that the impetus had come solely from the partner. Of course, this also speaks to the decline in the willingness of these women to initiate sex to their partner. Add to this young women's growing difficulties becoming aroused and the decline in the frequency of sexual intercourse, and we are approaching the core that reflects toward both sexual desire and the ability to have orgasms. When someone is not fully engaged in love making, it is no surprise that the enjoyment it brings is not what it used to be.

The persistent risk discourse may have created a situation in which women increasingly view sexual interaction through a more rational lens, rather than casting themselves body and soul into enjoying sexual experiences with a partner and realizing their own desires. Excessive rationalism is the biggest enemy of orgasms. Simply put, thinking does alight desire, but orgasms come when thinking ceases. The inability to implement this formula may be a key cause for the trouble that young women especially are increasingly having with orgasms.

The image that emerges from this study may bring solace to many who can now see that numerous others are just as inactive in bed as themselves, and that the sex other people are having is not that exotic. The label of postmodernism that accompanies sex in social discourse is absent in people's real, everyday lives.

Sex Offenders

Abstract

Social work with sex offenders operates at the intersections of sociology, psychology, and criminology. While key criminal justice and corrections agencies operate with convicted offenders, social work(ers) may be involved with unconvicted people who have behaved in a sexually harmful manner. Popular conceptions of the sex offender embodied in media reportage provide a distorted account. Psychological and sociological theories relating to the etiology of sex offending are reviewed and an integrated public health approach in which social work plays an important role is outlined.

Introduction

Social work practice with sex offenders is informed by both psychological and sociological research and theory. Psychological approaches focus on working with individual offenders whereas sociological perspectives locate sexual offences and sex offenders within a wider social context. This article considers both approaches and how they influence social work with sex offenders.

For the purposes of this article, the International Association of Schools of Social Work (IASSW) (2001) and International Federation of Social Workers (2012) definition of social work is adopted:

> The social work profession promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being. Utilizing theories of human behavior and social systems, social work intervenes at the points where people interact with their environments. Principles of human rights and social justice are fundamental to social work.
> http://www.iassw-aiets.org/international-definition-of-social-work

Applied to social work with sex offenders, this definition moves beyond the individual into a social and environmental context and it employs both psychological and sociological theories in its interventions with an emphasis on values. These aspects are referred to throughout this article. However, knowledge about people who commit sex crimes and the nature of their crimes is essential and Lancaster (1997) argues that teaching about sex offenders should form a part of every social work curriculum. She notes:

> The reality of child protection responsibilities means that social workers are inevitably brought into contact with people who have committed sexual offences, not just those who are offended against. A much more proactive and truly preventative stance could be developed by encouraging those at pre-qualifying stage of their training to engage with the difficulties of working with perpetrators of sexual abuse.
> (Lancaster, 1997: p. 93)

Lancaster points to the importance of understanding sex offenders for those working with victim-survivors: it provides insight into the victim-survivor's experience and sensitizes the social worker to potentially abusive scenarios within families and beyond. Building on the work of Lancaster, Myers (2008) agrees that knowledge about sex offenders is important for social workers and it is rapidly changing. He considers that knowledge about sex crimes and the people that commit them has a wider relevance in social work education beyond the mere subject matter, being particularly important in aiding reflection on the emotional impact of the work in relation to professional values and also in developing 'epistemic reflexivity.' In two exhaustive reviews of research, policy, and practice, Grady (2009a,b) highlights the central place that social workers in the United States play in working with sex offenders who may have a mental health diagnosis. Moreover, Grady and Abramson (2011: p. 441) note that the "likelihood of social workers in all practice settings finding themselves working with some aspect of sexual offending is a product of increasing sexual violence, which the World Health Organization (WHO) has described as a global crisis" (Krug et al., 2002). In their study of postgraduate social work education in the United States they point to "the increasing prospect that new practitioners, whatever their practice setting, will be called on to work with sexual offenders, offenders' families, or the survivors of sexual offenses" (Grady and Abramson, 2011: p. 441).

It is clearly important that social workers have knowledge and awareness of sex offending, therapeutic programs, and the values underpinning practice. The remainder of this article introduces these issues, but before doing so clarifies issues of terminology.

Definitions and Terminologies

> … terminology … is not simply a neutral statement of the situation, but reflects particular ideological and knowledge claims about the nature of the problem, its causes and consequent practices to deal with it.
> (Myers, 2008: p. 208)

Sex offenders are conventionally defined as people convicted of a sexual offense. In considering social work with sex offenders this definition is inadequate because only a small proportion of people charged with a sexual offense are convicted of that offense (Percy and Mayhew, 1997). Moreover, most people who

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28082-3

are sexually harmed by others do not report the incident(s), thus people who are convicted of sexual offenses are likely to represent the 'tip' of a far larger 'iceberg' (population) of people who sexually harm others. Percy and Mayhew (1997) estimate that the number of sex crimes committed is likely to be 15 times greater than the number reported to authorities. This distinction is important because, according to how social work is constituted and organized in different parts of the world, it is likely that social workers will be aware of unreported sex crimes and working with people who are sexually harming others but are not convicted of sexual offenses.

Moreover, across the globe legal definitions and penal responses to sex crimes differ considerably. Nelken (2009) points to the dangers in comparing systems of criminal justice by adopting either an ethnocentric approach or a relativist stance. He highlights (p. 294) the "Anglo-American tendency to assume what others do in foreign places and foreign languages is less important, and that they too are bound to come in line eventually," whereas a relativist approach considers comparison as a futile activity asserting that legal systems and criminal justice approaches only have relevance to the time and place where they operate. Jehle (2012) outlines the difficulties in studying attrition rates for reported sex crimes across Europe and in presenting credible comparative data.

Apart from the technical issues of definition there is a wider issue related to how professional discourses construct what they define. Social work is at the intersection of a number of very powerful professions; particularly psychology and psychiatry, where disciplinary discourses can obscure the fact, the people who commit sex offences are people. Writing of a commonly used word in the UK, Myers notes:

> 'Paedophile' is a particularly pernicious word in social work, which cannot fail to be used in a derogatory way *to reduce someone to their abusive actions*, thus locating the problem behaviour in deviance and psychopathology.
> (Myers, 2008: p. 208 – emphasis added)

This article is written in ways that recognize the humanity of people who sexually harm others. While the harmful acts that they commit are inhumane, these offenders are human. The point that Myers makes concerning the power of professional discourses to separate the sex offender from humanity is one that will be returned to later.

Understanding Sex Offenders: Moral Panics and Research Findings

The most common source of information about sex offenders is the news media (Jewkes, 2004) and much has been written about how the media represent the sex offender as a 'folk devil' whose particular threat creates a 'moral panic.' A folk devil is

> 'A condition, episode, person or group of persons [that] … become defined as a threat to societal values and interests …' and a moral panic presents the folk devil in 'a stylised and stereotypical fashion by the mass media; the moral barricades are manned by editors, bishops, politicians and other right thinking people.'
> (Cohen, 1972: p. 9)

Since 1991 there has been sustained criminological research into the construction of the sex offender as a 'folk devil' in the news media. There are four significant aspects to how the sex offender and sex crime are represented:

1. A stranger in a public place commits the sex crime. By implication people who are known to victims are unlikely to attack them and thus public space is dangerous and private/domestic space (i.e., the home/family setting) is safe.
2. The sex offender is a prolific offender who is offending and being reconvicted frequently.
3. There is no specific consideration of gendered issues.
4. There is little recognition of sex offending as a premeditated process.

Given the power of these representations, it is important to review research to explore their validity.

Stranger Danger: Dangerous Public Space Safe Domestic Space

In 2007, following a review of the research literature, the British Home Office (2007: p. 5) noted that 'the vast majority (at least 75%) of child sex offenders are known to their victims.' In relation to rape, Myhill and Allen (2002) found in their study of the 1998 and 2000 British Crime Surveys that 92% of women who were raped were attacked by someone they knew.

The Sex Offender as Prolific Offender

The view that most sex offenders invariably reoffend has regularly been contradicted by research findings. For example, the Minnesota Department of Corrections (2007: p. 7) note: "Contrary to popular opinion, sex offenders do not always recidivate. In fact, research has consistently shown that recidivism rates are relatively low for sex offenders." From their own data, they found that after 3 years, 7% of the 3166 offenders had been rearrested for a sex offense, 6% reconvicted, and 3% reincarcerated. By the end of the follow-up period (an average of 8.4 years for all 3166 offenders), 12% had been rearrested for a sex offense, 10% reconvicted, and 7% reincarcerated (Minnesota Department of Corrections, 2007: p. 2). Similarly, Harris and Hanson (2004: p. 7) using data from 10 follow-up studies of adult male sex offenders ($n = 4724$) examined 'sexual recidivism,' defined as new charges or convictions for sexual offences. They found that most sex offenders did not repeat sex offences, and that first-time sex offenders were significantly less likely to repeat sex offences than those with previous convictions for sex offences (19% vs 37% after 15 years). These rates are repeatedly found in studies and are strikingly low when compared to other types of offense. The UK Ministry of Justice (2012) published a longitudinal study of a generic cohort of offenders identified by conviction during January and December 2000. The cohort was made up of 480 000 people; 27.9% reoffended within 1 year, 38.9% after 2 years, 53.2% after 5 years, and 58.9% after 9 years (Ministry of Justice (2012)).

Although data, in the above study, are broken down in relation to age (i.e., 'young offender' and 'adult' offender), revealing higher rates for the younger group, there is no specific

breakdown of reconviction rates in relation to ethnicity. Although, there are indications from the USA (Alaska Judicial Council, 2011) that minority ethnic sex offenders have a higher reconviction rates than Caucasian offenders, this cannot be widely generalized and more detailed study is required in this area.

However, while reconviction data provide some indication of patterns of offending behavior they only refer to behaviors that have been processed through criminal courts, as indicated above much harmful behavior is not reported to any authority. It is very difficult to research and specify offenders' unreported sex crimes, although Soothill (2010), referring to recent US studies, points out that an initial conviction for sex crimes may make it harder for a person to avoid subsequent conviction.

Gender Issues

Kemshall (2004: p. 49), reviewing literature from the 1980s to the present decade, notes that "research consistently indicates that female sex offenders make up about 0.5% of all sexual offences against children." The numbers of female offenders who offend against adults are fewer than those who offend against children (Logan, 2008: pp. 491–492). Therefore, it is reasonable to note that men commit the majority of sex offences. Marshall (1997) estimated that by the age of 40, one in 90 of the men born in England and Wales in 1953 would have a conviction for a serious sexual offense. Moreover, it is likely that many of these men will know their victims.

Sex Offences as Premeditated Acts

Here research around the nature of 'targeting' and grooming is important. Olson et al. (2007: p. 241) describe grooming as "the subtle communication strategies that child sexual abusers use to prepare their potential victims to accept sexual contact." This involves controlling both the victim by concealing the threat posed and manipulating the environment to ensure that the offense will occur without disturbance. Campbell (2009: p. 432) highlights that grooming involves "strategies to present a specific image in an interpersonal relationship through the use of language that indicates the sender's 'persona' to the receiver." She identifies five particular grooming strategies employed by offenders (Campbell, 2009: p. 434): Supplication (presenting a helpless public persona); Intimidation (presenting a powerful or harmful persona); Self-promotion (presenting as competent); Ingratiation (presenting likable or affiliative behaviors); Exemplification (presenting a self that is worthy – demonstrating high moral values). The process of offending is both conscious and premeditated; it does not, as many men in therapy groups have said, 'just happen.'

While empirical data can challenge commonly held assumptions about sex offenders, it has also been systematically used to develop and refine theories related to sex offending. Psychologically based theories have primarily been used to develop more effective therapies. Theories that have a more sociological origin have the potential to influence wider social/public policies, however all theories are socially and culturally located. These issues are reviewed in the next section.

Understanding Sex Offenders: Key Theoretical and Therapeutic Approaches

Theories that seek to understand or explain sexual offending are not merely heuristic devices; developed theories suggest ways of reducing sex offending. Psychological theorizing concentrates on the individual offender and seeks to identify (more) effective therapeutic approaches to reduce the risks posed by individual offenders. The ultimate objective of psychological theory is to improve the clinical response to sex offenders. Evidence for an improved clinical response is complex but much attention is focused on reconviction rates. Sociological (including social anthropological) theories consider sex offending as a social phenomenon. The ultimate objective for sociological theory is to locate sex offending as a social problem that requires a social/public policy response. In many ways, social work is located across the boundaries of these two perspectives in that social workers work with both individuals and with communities, and in some cases they adopt a campaigning role about social issues.

Psychological Perspectives

From a psychological perspective, the works of Ward and colleagues are of key importance (e.g., Ward and Maruna, 2007). This work has been concerned to analyze and develop psychological theory in relation to understanding sex offenders. Ward and Hudson (1998: p. 47) noted:

> The major task of a good etiological theory of rape, child molestation, or any other form of sexual offending is to account for its onset, development, and maintenance.

They also noted that there were three different types of theory that sought to explain sex offending:

- Level 1: multifactorial theories offer a complex account of the etiology and continuance of sex offending.
- Level 2: single factor theories focus on one issue to account for the etiology and continuance of sex offending.
- Level 3: micro-level or offense process theories give particular attention to an aspect of offending behavior.

In the mid-/late twentieth century single factor theories were common and often in conflict with one another. For example, feminist theory and evolutionary psychology theory are both described as single factor theories. The former asserts the key importance of patriarchal social conditioning of men; and the latter emphasizes the importance of physiological urges to perpetuate 'the species' (for a review of these issues, see Travis, 2003). Micro-level theories explore specific aspects of the detail of offending behavior and develop appropriate therapeutic strategies. However, the theories that have had increasing influence are multifactorial theories that incorporate the following dimensions: physiological, psychological, emotional, situational, historical (fixed), and current circumstances in accounting for sex offending. A key aspect of these theories is that they have been developed from analyses

of empirical studies of sex offenders, their personal histories, and their offense patterns.

Within the development of this research, the work of Bonta and Andrews (e.g., Andrews et al., 1990, 2011) is of great significance. Their work has focused on identifying factors associated with risk of reoffending and 'criminogenic need' became a key focus of research during the 1980s. Using statistical analytical techniques, they began to identify that both personal history and current circumstances were relevant to understanding risk of reoffending. Historical unchangeable factors (such as childhood events, or criminal convictions) were considered to be static factors that may relate to (re)offending, while current circumstances (e.g., family/intimate relationships, level of education, employment, accommodation, use of leisure time, use of substances, and social relationships) also had a crucial bearing on the likelihood of (re)offending. These latter circumstances were construed as dynamic risk factors because they were amenable to change and linked to (re)offending. These areas were known as areas of 'criminogenic need,' that is, they are related to the start and continuance of criminal behavior, but if they could be changed they might lead to the cessation of criminal behavior.

While Andrews and Bonta's work recognized the importance of static factors in offending, it did not seek to offer an etiological account. Rather, it focused on key issues in current circumstances that were amenable to change and from this focus developed the 'Risk-Need-Responsivity' (RNR) treatment model. There have been other important attempts to offer multifactorial accounts of sex offending, for example, the confluence model of sexual aggression; integrated theory; quadripartite model of sexual aggression; the four preconditions model, the pathways model (for a full review of these approaches see Beech and Ward, 2004) and the Integrated Theory of Sexual Offending (Ward and Beech, 2006). Beech and Ward (2004) have highlighted the importance of developing credible and coherent theories that account for the onset and continuance of sexual offending, for without such theories, they suggest therapeutic programmes and risk assessments are flawed. McNeill (2012) has recently highlighted that these approaches are theories of the *etiology* of sex crime and suggests that more recent theorizing about *desistance* from crime may be of greater value in helping sex offenders to refrain from committing further offences.

In recent years there has developed a considerable body of criminological research in relation to general desistance from crime. Farrall (1995: p. 56) notes "most of the research suggests that desistance 'occurs' away from the criminal justice system. That is to say that very few people actually desist as a result of intervention on the part of the criminal justice system or its representatives." Ward and Maruna (2007: p. 14) comment that it "makes considerable sense to develop models of rehabilitation on the basis of what is known about how reintegration works in the 'natural' environment outside of the criminal justice system." McNeill (2012) notes that there have been three separate perspectives on desistance that are increasingly becoming integrated: (1) the significance of age and maturation; (2) life transitions and social bonds; (3) personal and social identity. With the theoretical focus on what enables an (ex)offender to live a crime-free life attention is focused on slightly different issues, for example, what is a positive lifestyle and how is it attained?

The two dominant psychological approaches to working with sex offenders in the West are the 'RNR' model (Andrews et al., 2011) and the Good Lives Model (GLM) (Ward et al., 2012). Both models assert that they are underpinned by a multifactorial theory of sexual offending and that their interventions are well evidenced. The two models appear to be competing for therapeutic hegemony in the West and the above two papers neatly encapsulate the differences in the models. Both models recognize the importance of assessing risk and link therapeutic programs to identified areas of risk. Advocates of GLM assert that RNR is overpreoccupied with identifying and policing offender risk and ignores the positive potential all offenders have to live a 'good life' (with help). Advocates of RNR assert that there is little empirical evidence available to support the assertions of the efficacy of the GLM model. They also suggest that the GLM does not give sufficient careful attention to identifying and managing risk. Advocates of both approaches vigorously refute criticisms and cite counterevidence.

Sociological Perspectives

Psychological and criminological theories in relation to sex offending focus primarily on the individual offender and seek to link understandings of the 'cause' of offending and desistance to the development of therapeutic programs. Sociological theories widen the focus and consider sex offending as a social rather than an individual phenomenon. Theories reviewed so far are largely based on an understanding of sex crimes that is dependent on and contained within the processes of criminal justice systems. Both 'criminogenic need' and 'desistance' are identified from research on convicted sex offenders. Sociological (including feminist) theorizing of sexual offending looks beyond the individual offender and beyond the criminal justice system. These perspectives are particularly important for social work(ers) to consider because social work often engages with people who have sexually harmed others but have not been convicted of such acts.

Feminist theory recognizes that sex crimes are rarely reported and those that are reported rarely result in a conviction. Kelly et al. (2005) note that findings from the 2001 British Crime Survey indicated that, by the age of 16, 7% of women had suffered at least one serious sexual assault. Five percent had been raped. The study also looked at attrition in relation to rape crime reports (i.e., rapes reported to the police) and rape convictions. They found that of 3527 crime reports of rape only 8% resulted in a conviction. Similar patterns of attrition are noted in relation to all sex crime reports across Europe and beyond (Jehle, 2012). Feminist theory not only widens consideration of sex offences, it also challenges overdependence on what is legally defined as a sex crime. Kelly (1988) presented qualitative data from 60 women who had experienced some type of sexual violation, and from this material she developed a continuum of sexual violence that ranged from unwanted nonphysical approaches through to rape. Kelly's continuum has continued to be a very

influential framework for recognizing and understanding the place of coercive sex within a wider range of personal relationships. Gavey (2005) makes use of this framework in her powerful presentation of the commonplace nature of sexual coercion within Western cultures.

However, the work of Sanday (2003) is of central importance in theorizing sexual offending in a social context. In her work spanning three decades, she has drawn attention to the characteristics of 'rape-free' and 'rape-prone' societies and communities. Whilst some of her work involves comparative anthropological studies of differing societies, she also studied fraternity houses in universities of the United States. Having carefully reviewed her comparative data she notes:

> 'Rape-free' societies, gender relations were marked by respect for women as citizens, significant female power and authority, and the near absence of interpersonal aggression in social relations … 'Rape-prone' societies, social relations were marked by interpersonal violence in conjunction with an ideology of male dominance enforced through the control and subordination of women. … Faced with such data the only reasonable conclusion by empirically minded social scientists must be that culture plays a role in the expression of male sexual aggression.
>
> (Sanday, 2003: p. 337)

Her conclusion is further substantiated by a group of psychological studies, sometimes known as 'rape proclivity' studies. In this area of research, male undergraduates in North American Universities were asked if they would rape if they were guaranteed that there would be no negative consequences for themselves (e.g., criminal prosecution). A consistent finding in these studies is that between 25 and 30% of respondents indicate that they would rape (Cowburn, 2005). Furthermore, a British study (Burton et al., 1998) involving young people ($n = 2039$) found that young men thought it was acceptable to force a woman to have sex in specified circumstances: if she was his wife; his long-term girlfriend; if he was 'so turned on he could not stop'; if nobody would find out; if he had spent lots of money on her; or if she had slept with many men. Another British study (Burman and Cartmel, 2006) of young people's attitudes found that a third of young men and a sixth of young women thought that using violence in intimate relationships was acceptable under certain circumstances.

Emerging from this work, there has also been a growing body of profeminist scholarship. Mac an Ghaill studied young people at secondary/high school, and identified the influences of 'compulsory heterosexuality, misogyny, and homophobia' (1994: p. 9) in shaping young masculine identities. The juxtaposition of compulsory heterosexuality and misogyny points strongly to values and attitudes that support sex offending. Increasingly, men and their behaviors are being placed at the center of attempts to understand sex offending (see, e.g., Dominelli, 1989; Cowburn, 2006).

Theories that do not look beyond clinical utility are limited because sex offending is not confined to a discrete population of offenders, whose risk can be reduced and who can be supported in their desistance from offending. While some sex offenders may receive effective help, there is always a new population emerging. In researched populations of sex offenders, where conviction data are presented, the majority have no previous offences (Cowburn, 2005). Thus, dealing with people who commit sex offences requires more than clinical excellence, it requires consideration of the population of people who harm others without being convicted and it requires consideration of sex offending at a social/public policy level.

Ward and Hudson (1998) comment that 'a good etiological theory' of sex offending should account for 'its onset, development, and maintenance.' While both Andrews, Bonta, and colleagues and Ward and colleagues note the importance of the social context and cultures wherein offending occurs, this is given little or no sustained attention in their theories of sex offending or therapeutic programs, which focus on individual offenders but do not consider social identities; for example, gender, ethnicity, and class. Given that sexual offences occur in social contexts that may contribute substantially to their onset, development, and maintenance, a comprehensive theory must incorporate social and cultural issues and aim to improve not only therapy but also social/public policy responses to sex crime. It is at the intersection of these areas that social work and social workers are involved with both convicted and nonconvicted sex offenders.

Responding to Sex Offenders: Rehabilitation, Public Health, and Social Work

> Rehabilitation, therefore, is not just about sorting out the individual's readiness for or fitness for reintegration. It is as much about rebuilding the social relationships without which reintegration is impossible. Any would-be supporter of rehabilitation has to do more than sort out 'offenders'. S/he needs to mediate relationships between people trying to change and the communities in which change is impeded or impelled; as well as mediate the role and limits of the state itself in the process.
>
> In sum, my argument is that, viewed from the perspective of desistance theory and research, individual-level psychological theories, analysis and prescriptions are best seen as a necessary but an insufficient part of developing an integrated theory of rehabilitation.
>
> (McNeill, 2012: pp. 13–14)

Social work with sex offenders is about both the individual rehabilitation of the sex offender and development of safer communities. The opening quotation from IASSW strongly highlights the personal and the social orientations of social work. Social workers work with people, while seeking to promote social change. Social workers use both psychological and sociological theories to inform their work, which is underpinned by values of human rights and social justice. However, these aspirations may take varying forms according to the professional context in which social workers operate. In relation to working with sex offenders, social workers may be required to work in a correctional setting, in a child and family setting, or with vulnerable adults. In all of these settings, social workers will be required to understand and assess what is happening and respond in an appropriate manner.

The theories and models of sex offending described above focus on individual risk, individual rehabilitation, and the social context in which offending occurs; potentially social

work is involved in all of these areas. Thus, social work is about more than just the rehabilitation of an individual offender; it is about facilitating change at both an individual level (desistance) and a social level, highlighting and changing endemic social and cultural attitudes that support sex offending. In the early years of twenty-first century, there have been attempts by both academics and governments to integrate individual and social perspectives in developing strategies to reduce sex crimes. Richard Laws, a prominent North American clinician and academic, has developed a three- tier 'public health approach' to sex offending. He suggests that it is necessary to (1) prevent harmful behavior from starting; (2) quickly address early signs of coercive/harmful behavior; and (3) provide treatment programs for people who have been convicted and are in the criminal justice system (Laws, 2008: p. 612). The strength of this model is that it acknowledges and addresses both actual sexual harm and the potential to harm sexually that is outside the jurisdiction of the criminal justice system. The challenge for social work is to operate effectively at all levels within this model.

Abstract

This article reviews major theories and empirical evidence on the development of sex (or gender) role. Gender role is different from sex; it is more about the socialization process of what and how men and women should behave. Biological, evolutionary, cognitive developmental, and social learning theories are first described to explain formation of gender stereotypes and gender schemas, followed by discussions on how family, education, workplace, media, and cultural settings would further reinforce the preexisting gender role. Bronfenbrenner's ecological theory is applied to conclude how different social contexts interact and impact on the development of gender role.

Ever since we had knowledge on genetics and the sex chromosomes, gender and sex identification have become not only clearer but also more complicated. The XY sex determination system differentiates the two sexes on the 23rd pair of chromosomes, where males have the XY combination and females have the XX combination. Still, there are cases when individuals are born with other combinations, such as XO (having one X chromosome only) XXX, XXY, or XYY chromosomes (for review, see Blackless et al., 2000). The ambivalence is also seen in external genitals, a much more common clue we rely on in determining newborn babies' gender. Some babies are born with inconsistent internal and external genitals, external genitals that resemble both sexes, or ambiguous genitals. Intersexed babies or children have usually undergone surgeries for 'correction' of their genitals to fit the binary differentiation of the two sexes. Nevertheless, one's sexual identity or gender role seems not to be easily manipulated. One of the most famous cases in how 'assigned sex' does not work would probably be the case of David/Brenda Reimer (1965–2004). David was accidentally castrated when he was 7 months old. To correct the surgical failure, his parents made him undergo hormonal and surgical treatments, and raised him as a girl, Brenda. Not knowing that she was actually a boy, Brenda still preferred to and acted like a boy. At the age of 15, he was told the truth and eventually received multiple surgeries and hormonal treatments to rebuild his penis and manhood. Living his whole life struggling to fit in the role being a male or female, David ended his own life at the age of 38 (Wood, 2011). The tragic story of David Reimer implied two things: (1) biological or genetic factor probably plays a crucial role in defending ones' sexual identity or sex role and (2) the binary definition of sex does not always apply to everyone and may cause unnecessary pain to certain individuals.

Sex, gender (or sex role), and sexual orientation (or sexuality) are constructs that are usually viewed as consistent with each another. In most cultural settings and most of the time, people expect males to process a male sex role, perform in a masculine way, and be interested in females, while females are expected to process a female sex role, perform in a feminine way, and be interested in males. Sex is expected to be binary: a person can be either male or female. However, this is not always applicable to everyone. Besides intersexed individuals, there are also transgendered individuals, who endorse sexual identities that are opposite of their biological sex.

Sex is binary most of the time, but gender is not. Gender refers to how individuals express themselves; even it does not fit into ones' biological sex. Sexuality is also not necessarily to be consistent with one's sex. Compared to biological sex, gender is more about the socialization process of what and how men and women should behave. In other words, it is how one does rather than whom one is. Still, biological sex is inseparable from gender. Biological factors potentiate individuals to behave, while gender allows a flexible variation and input from the environment (e.g., learning experience). If a baby is born to be biologically male, external forces, such as the parents and school, would exert forces at different level to direct his gender schema and behaviors.

In the following sections, several major theories and related empirical evidence are considered.

Biological Factors

The word 'gender' apparently refers to differences rather than similarities between the two sexes. There has been a long history that scholars tried to trace gender differences to the fundamental biological differences. Recent research evidence has supported the genetic effect on sex role and related behaviors. Very often, the society encourages sex typing of children so that they learn their prescribed roles very early. Sex-typed behavior means babies would show different patterns of behavior according to their sex, even earlier than they develop any concrete ideas about gender (Boyd and Bee, 2012). As early as 18–24 months, infants already show some preference over toys for their gender (Thommessen and Todd, 2010). Some children, however, exhibit gender atypical behaviors (GABs) that have attracted attention from psychologists. Knafo et al. (2005) examined the genetic and environmental effects on GABs by studying 5799 twin pairs (3- to 4-year-old twin pairs). Gender atypical children were defined

as those who had high affiliation with the opposite sex roles and behaviors (i.e., feminine boys, masculine girls). The researchers found a modest genetic influence on boys' femininity (37%) and a strong genetic influence on girls' masculinity (82%). The effect of shared environment was much stronger for gender atypical boys (42%) than for such girls (0%). One plausible reason is that parents (and the society) are more tolerant of the boundary crossing of girls than boys, so that they put more effort (external forces) to socialize their sons to adopt masculinity. The genetic effect on GABs was also found in other age groups (7- and 10-year-old children, van Beijsterveld et al., 2006).

One major implication of GAB is its effect on the development of sexual orientation in adulthood. In a recent study, Alanko et al. (2010) reported that GAB in childhood shared common genetic background with that of homosexuality in adulthood, which was stronger for men than women. Bem's (2000) exotic becomes erotic theory suggests a provocative explanation of the linkage. Accordingly, GAB is theorized as an arousing agent because gender atypical children are often alienated by same-sex peers. As one grows up, the physiological arousal may be misattributed to erotic attraction to the same-sex teasers, thus causing homosexuality. As the alienation (and thus physiological arousal) is often stronger for boys, it is not surprising why the GAB-homosexuality linkage is stronger for male.

Two limitations are observed for genetic studies on sex role behaviors. First, although genetic factors account for the development of (atypical) sex role, the specific effective genes are not identified yet. Would it be the same as the 'gay' gene (i.e., the Xq28 region, Hamer et al., 1993, which is inconclusive either)? Without knowing the effective genes, it is impossible to know how genetics transfers its effects to gender role behaviors. Furthermore, gender role (a)typicality is by itself a relative construct that is under the impact of environmental forces. Nothing can be atypical unless there is something that is commonly endorsed (i.e., typical). In view of this, macro-level factors, such as culture and religious beliefs, may play more crucial role in the development of sex role.

As mentioned in the aforementioned paragraph, there are occasions that individuals are born with variations in their XX or XY chromosomes. Wood (2011) and Pressley and McCormick (2007) summarized studies on how cognitive or physical attributes may be affected by hormones or chromosomal combinations as follows: individuals who have XXY chromosomes (Klinefelter syndrome) tend to be taller but with less androgens, and they may exhibit lower spatial abilities but with normal intelligence quotient; individuals who have XO chromosome (i.e., one X chromosome only; Turner syndrome) may not have usual puberty changes and may show poorer spatial skills. Girls with XXX (triple X girls) may be taller than other XX girls, and they have normal puberty and intelligence. In addition, sex hormones and differences in using different lobes of brains between the two sexes are generally believed to be related to some differences between men and women. Nevertheless, previous research on the gender differences of cognitive abilities was inconclusive (e.g., Hyde et al., 1990). In addition, the modest differences seem to be a result of environmental factors more than one's biological sex.

Evolution and Selection of Sex Roles

According to Charles Darwin's theory of evolution (1859), the traits of a species evolve as a result of adaptation to environmental challenges. Individuals who have developed the more adaptive traits are more likely to survive and reproduce, thus passing the traits to the next generation. In other words, challenges from Mother Nature decide which traits to be augmented, diminished, or modified within a species (i.e., natural selection). Over the past two decades, such an idea has been extended to understand human behavior, especially gender roles and sexual behaviors. Evolutionary psychology, as the name suggests, seeks to explain individual differences based on the evolutionary history of our species.

Evolutionary psychology (see Buss and Schmitt, 2011, for review) holds that the psychological mechanisms we currently have are the results of ancestral adaptation. Reproduction is of particular importance because it determines what traits, be it physical or psychological, can be passed to the offspring. In this regard, the different reproductive systems of men and women pose different challenges and economic tradeoffs to them, leading to different sexual behaviors and strategies. Men, whose reproductive system features mass production of sperms and longer active period throughout the lifespan, have little cost in impregnating women. The fact that they do not necessarily need to bear their children also reduces their parental investment. As a result, men usually prefer short-term sexual relationships and multiple sexual partners. In contrast, the reproductive and parental costs of women are much greater: the ova are far rarer in a woman's lifespan, and much resource is devoted to bearing and raising a child. As such, a supportive and committing long-term partner is more important for women to attain reproductive success. It is believed that the different sexual strategies determine why men and women adopt different gender roles. Buss and Schmitt (2011) summarized abundant studies that were believed to support the sexual strategies theory. To sum up, the studies showed that men were more likely and willing to have multiple, short-term sexual relationships with strangers than women. However, it is questioned whether these findings are direct support or just a circular argument of the theory. While the sexual strategies theory aims to explain the different mating strategies of men and women, finding that the two sexes actually differed is but a reiteration of its origin. If gender behaviors and roles are evolved, the most direct evidence should show how the changes occur. In biology, this is attained by fossil records of different species sampled from different layers and periods. Such evidence is seemingly absent in the evolutionary psychology literature.

If gender role is a result of adaptation to reproductive challenges, the aforementioned gender differences should be observed irrespective of the context one is in. In other words, the observed gender role differences should be universally true across different cultures. While earlier studies supported this cross-cultural universality (e.g., Schmitt, 2005), recent research has provided opposite evidence. For example, Perrin et al. (2011) investigated four love and sexual behaviors that were expected to be different across men and women, but only reported a significant difference of desires for relationship support. Moreover, the difference was largely explained by

individual's gender role identity (masculinity vs femininity), implying that the difference is a result of gender role socialization. In a later study, Zentner and Mitura (2012) compared the gender differences in mate preferences across societies of different levels of gender equality. The expected gender difference from evolutionary theory was only observed in nations of low sexual parity (e.g., Turkey, Korean Republic). The difference declined as the gender inequality gap decreased (e.g., Finland, Philippines).

It should be noted that by evolution, Buss and Schmitt (2011) did not assert that gender roles and behaviors are purely genetically determined. If certain gender roles are inherited across generations, it can be 'selected' through nongenetic mechanisms, such as gender role conformity, social conditioning, modeling, and reinforcements. Still, the social constructionist perspective would question whether such a selection theory overinterprets and complicates the simple social influence. For example, the social pressure to conform to gender norms may be termed as a selection of the trait, which in reality does not contribute to the understanding of the gender issues. Meanwhile, it is hard to totally refute the role of genetics in determining gender roles, as reviewed in the previous section. Regarding the biological and evolutionary theories, more direct evidence is required on how gender roles are acquired through biological mechanisms. In the following, we discuss the other side of the argument – the cognitive and social view on gender roles.

The Development of Gender: Cognitive Developmental Theories

Kolhlberg (1966) suggested a cognitive developmental theory on understanding the gender development in children. By the age of 2 years, most infants can identify themselves as boys or girls, which is the first step of forming gender identity. Children gradually understand that gender is something stable and that they would remain as either boys or girls. They have insights about how physical features define the gender of individuals and gain gender stability. For instance, men are those in beard and short hair, while women are those in dress and long hair. Sometimes, children make mistakes by thinking that external outfits will change the gender for individuals; they may think that if a boy wears a dress and lipstick, he will turn into a girl. Such confusions on gender identity among young children reflect their limitations in cognitive functioning, and this can be explained by applying Piaget's (1977) theory. According to Piaget (1977), children in the preoperational stage usually lack the awareness of conversation, which hinders them from maintaining a constant identification of an object with changing appearances. It is usually by the age of 5–6 years that children would attain gender constancy, so that they understand that gender does not change along with physical appearances and that their gender will remain unchanged in their whole life.

The attainment of gender stability and constancy signifies the beginning of the socialization and social learning of gender roles. By identifying themselves as either boys or girls, children learn the appropriate behaviors and preference of their gender and form gender schema, which is a "packet of gender-relevant information, understanding, knowledge, and beliefs" (Levy and Fivush, 1993: p. 132). Such a mental structure affects how gendered information is filtered, processed, and reacted to. Preschoolers make inferences of what people should do based on their rigid gender schemas. Behaviors that violate the schemas become taboos and are avoided (e.g., boys should not play with dolls; girls should not play with guns). The violation of gender schemas is also avoided by limiting plays with same-sexed playmates (vs opposite sex ones) only (e.g., Martin and Little, 1990). The development of gender schemas continues as children age, when they gradually understand the complexity and flexibility of gender roles. In the following, we discuss how gender schema is organized and the different sources that contribute to its formation.

Knowledge of Gender Roles and Behaviors

Gender schemas and stereotypes are important sources of knowledge that guide our behaviors in a gendered context. They allow us to make quick judgments on people and situations based on gender. According to gender schema theory (Bem, 1981), masculinity and femininity are often unconsciously applied to different occupations and activities. To name a few, ballet dancers, flight attendants, and nurses may often be assigned to the feminine schema, while warriors and soldiers are often assigned to the masculine schema. Consider the naming of the *X-Men*, which is a team of mutant superheroes (both men and women) that fights against different evil parties. It would probably be against most people's gender schema when the team is renamed as *X-People*, or the heroines are called *X-Women*.

How is gender knowledge organized in the human mind? Apart from masculinity and femininity, recent research has supported a general model of social cognition that may bring insights into research on gender schema and stereotypes. Fiske and colleagues (see Fiske et al., 2007, for review) theorized two fundamental stereotypes in social cognition, namely, warmth and competence. According to the researchers, the two universal dimensions of perceiving individuals and out-groups serve survival purposes. The warmth stereotype is assessed first, which determines whether the others are friendly or not. Being the primary stereotype, perceived warmth determines whether one would help (active facilitation) or attack (active harming) the perceived. The competence stereotype is then assessed, which tells whether the others have the ability to execute their intentions. Perceived competence, the secondary stereotype, determines whether one would associate with (passive facilitation) or neglect (passive harm) the target. In social cognition, perceivers would map the target according to the two stereotypes and thus lead to different behavioral and affective responses.

The two fundamental stereotypes, when combined, predict different emotions toward the perceived individual or outgroup (Cuddy et al., 2007). When high warmth is paired with high competence, admiration is induced, which leads to univalent facilitation (both active and passive) with the perceived. Another univalent emotion happens with low warmth being paired up with low competence, which results in univalent downward emotions (e.g., contempt) and harming

to the perceived. Ambivalent emotions and behaviors are predicted when either dimension is high. For instance, a group is pitied when it is perceived with high warmth but low competence. This combination leads to active facilitation (helping), but also passive harm (negligence). On the other hand, a group is envied when it is perceived as highly competent but low in warmth. This combination leads to passive facilitation (association) due to its competence. However, the perceived unfriendly intent also attracts active harm (attack).

The fundamental stereotypes of warmth and competence may be applied to gender schema and explain how and why people react to men and women differently in the society. For example, Fiske et al. (2002) used cluster analysis to illustrate how several gendered identities are perceived differently on the two stereotypes. The research showed that housewives are perceived as warm and incompetent, sexy women and gay men are perceived as more competent but less warm, and business women, men, as well as rich and educated people are perceived as most competent but low in warmth. It should be noted that the stereotype map differs across sample of raters and time (see Cuddy et al., 2007).

Although the work by Fiske and colleagues did not intend to study gender perception, the model shows resemblance to gender schema theory. The warmth dimension is analogous to feminine communal traits, while the competence dimension is analogous to masculine agentic traits. Still, the two stereotypes have important implications on gender roles research. First, the theory makes clear prediction on how warmth and competence influence one's affective and behavioral responses to the perceived target. It also highlights the possible ambivalence of social perception, that one can exhibit both facilitation and harm to the perceived target (i.e., pity and envy). Based on this model, future research may investigate how different gendered groups are mapped differently on the two dimensions by individuals of different cultures, socioeconomic status, and gender.

How Gender Is Acquired

Family Factors

Language is an important media for the acquisition of gender roles. Parents, who are socialized with gender schemas, transfer the knowledge to their daughters and sons through different verbal responses. Early studies (e.g., Cherry and Lewis, 1976) have reported that mother–daughter communication features two-way communication (e.g., asking questions, making interpretation), while mother–son communication is dominated by one-way communication (e.g., giving instructions and explanations). Interestingly, Clearfield and Nelson (2006) reported that the different communication styles toward daughters and sons occurred as early as 6 months of age, when the infants were not able to speak yet. The observed mothers also engaged more in the play of their daughters (vs sons), which may subtly encourage social interdependence to them. Fathers, on the contrary, generally have more physical play with their children (e.g., Lindsey et al., 2010).

Parents are perhaps the first source for children to learn gender schemas or stereotypes. From birth, parents treat babies differently based on their sex. Wood (2011) suggested that by conveying different messages to little girls and boys via daily conversations, children learn their gender identity. Children compare their own behavior and contrast it with their parents' behavior and expectations and take up the gender-appropriate behavior. For instance, parents tend to play masculine toys with boys and feminine or neutral toys with girls (Wood et al., 2002).

Social Learning and Observational Learning Theories

The social learning theory (Bandura, 1977) suggested that children imitate others for the appropriate gender roles and behaviors. While children are prewired to imitate whatever comes to their attention, rewards and punishments may moderate whether the learning is successful. Reward, be it direct or vicarious, is applied to reinforce gender-appropriate behaviors. For instance, parents tend to have more rough and tumble plays with boys (vs girls); parents also tend to provide gender-appropriate toys to their children (Levy, 1999), and show more acceptance to boys expressing anger than to girls doing the same (Zahn-Waxler and Polanichka, 2004). Parents are generally less tolerant to cross-gender behavior, which means behaving in an atypical manner to one's gender, among boys than in girls. Boys are more likely to be punished for not being masculine than girls being not feminine, or having gender role transgression (e.g., Sirin et al., 2004). As boys grow into men, studies found that men experience more gender role anxiety than women (Vandello and Bosson, 2013). This might be explained by the social learning theory, as men tend to receive punishment for not showing manhood since young age. As mothers are usually the primary caregivers of children, mothers tend to relate themselves more to daughters than to sons. When boys cannot fully identify themselves by modeling mothers, they recognize themselves as being different from mothers (Wood, 2011). Vandello and Bosson (2013) argued that in most cultural settings, boys can only adapt to 'snormal' or 'healthy' male gender roles by separating themselves from their female caregivers, and to avoid femininity by their best efforts to show that they perform, behave, and think differently compared with females to gain manhood.

As children grow up and build broader social connection outside the family, the learning models and rewards are extended, mainly in school settings. Eder et al. (1995) found that in middle schools, males and females are reinforced differently and they therefore may pick up different gender roles. For instance, males are reinforced by both peers and teachers as being athletes, while females are not; males are encouraged to act aggressively, again by teachers and peers; compared with boys, being physically attractive is valued among girls, while physically unattractive girls are more likely to be picked on; sexually active girls receive defaming comments, while sexually active boys receive social praise and approval; heterosexuality is widely accepted in middle schools; and those who do not act according to the widely accepted gender role would be socially rejected. Teenagers may be socialized to adopt the accepted gender role by conforming to the norm. Any preexisting differences in gender role are further strengthened by observing the hidden rule and reinforcing (or punishing) by following or violating them.

Media

With increasing autonomy and literacy, children may acquire gender schema through more channels other than their parents. In a recent study, Fitzpatrick and McPherson (2010) studied the gendered content of 56 coloring books published in the United States. The researchers reported that male (vs females) characters were more likely to be portrayed as authoritative figures (e.g., adults, superheroes) and showing more gross motor actions. Female characters, on the other hand, were often depicted as static and humanlike. It was noted that most of the printed characters also appeared in other popular media, such as movies and cartoons. This implies that the acquisition of gender schema may also occur in other media. Meanwhile, adults seem to have a selection bias toward gender-typed media such that their gender schemas can be self-reinforced (Knobloch-Westerwick and Hoplamazian, 2012). The researchers reported that both biological sex and gender schemas (masculinity vs femininity) predicted the gender-typed magazines that one would pick. The selection bias also appeared to reinforce the prescribed gender schema. The self-reinforcing nature of gender schema explains why the vicious cycle between gender schema and gendered behavior is so difficult to break.

Gender Role Expectations, from the Education System to Work

Gender role expectations affect how males or females perform in educational settings. "Test performance depends on the test taker's characteristics, as well as the test taker's interpretation of the testing situation" (Massa et al., 2005: p. 109). It has been found that for an embedded test on spatial ability, when men's performance was not affected by their gender role, females who held feminine role performed better when the same embedded test was framed as measuring empathy; on the other hand, when the test is framed as measuring spatial ability, females who held masculine role performed better (Massa et al., 2005). This suggested that gender role is highly relevant to how students view themselves, which may then affect how confident (or well) they perform on cognitive tests in certain ways to make their performance consistent with their assigned gender roles. Stereotype threat may hinder one's educational performances. When women are presented with stereotype threat that women did worse compared with men on a test on math ability, they tended to perform less well (Spencer et al., 1999).The internalized stereotype threat may not only hinder one's performance in schools but also influence the choices males and females make in education.

Despite the fact that differences in actual test scores in math or science tests between male and female students are small, female students tend not to be as confident as male students in their performance in math or science. Pressley and McCormick (2007) summarized a number of findings and suggested that parents and teachers tend to 'cooperate' in decreasing girls' confidence in math or science subjects. For instance, parents tend to offer less help to their daughters than sons; they tend to undermine their daughters' abilities in math and science subjects but care about and encourage their sons' performance in math or science subjects more. Teachers also tend to give less help to girls in class and are more responsive to boys' questions. Boys on average received more interactions with teachers for science or math classes.

For a long period, people held strong stereotypes toward educations for males and females. Compared with boys, more girls are illiterate, do not have access to education, or have narrower choices of education (Silberstang, 2011). This may be related to gender stereotype, cultural ideology, or religious practice. More women are doing lower paid jobs or earning less than men. In less than 100 years ago, women were expected to take 'woman subjects', such as home economics only. In developed countries where gender equality is emphasized, females were gradually encouraged to take up more professional jobs such as social work and teaching (Silberstang, 2011). In 2010, although females graduated with bachelor degrees in the United States outnumbered males (954 891 women vs 713 336 men), 'sex tendencies' in professionals are still present. In the United States, men graduated with the more traditionally 'male' subjects, such as degrees in computer and engineering, outnumbering women for 4 to 5 times, while women graduated with the more traditionally 'female' subjects, such as psychology and outnumbered men for 3 to 4 times (National Science Foundation, 2010).

Women working in traditionally 'male-dominated' settings, such as engineering, may also face more difficulties as stereotypes on women being less competent in these professionals are still held. If women do not perform exceptionally well in 'male-dominated' industries or professionals, they would be viewed as incompetent; however, if they excel, they would be viewed as selfish, cold, and not being welcomed by colleagues (Dean, 2006). Despite the fact that more females than males are awarded with bachelor degrees, fewer females become faculty in academia or take up senior executives post (Silberstang, 2011). For instance, the most 'productive' time for junior faculty members to accumulate publications for attaining tenure collides with the most 'reproductive' time of female faculty members. Rhoads (2010) argued that when both males and females are entitled to maternity leave, male faculty members can make use of the leave to produce papers, while female faculty members cannot as they have to carry out duties as mothers. The worst label to a woman is 'being a bad mother' (Chrisler, 2013). Both the gender role stereotypes on women's abilities and the biological limitations that females have shorter reproductive period compared with men may result in a glass ceiling effect in workplace. Women are more often to face with challenges in work–life–family balance as they are expected to be nurturing, kind, and less motivated to earn money but be more interested in family life. Such widely held beliefs strengthen the preexisting gender inequality from schools to workplace. The biological limitations, gender stereotypes, and cultural expectations for women to devote more time and energy on the 'mother track' would ultimately affect women's upward mobility.

Bronfenbrenner's Ecological Theory and Sex Roles

Bronfenbrenner's ecological theory (1993) is applied here to conclude the development and reinforcement of existing sex roles in a given society. The framework of ecological system emphasizes the bidirectional influences between individuals' characteristics and the different environmental contexts surrounding individuals. There are several 'systems' or

Table 1 Summaries and comparisons of different theories concerning sex or gender role development

	Biological or genetic factors on determining sex	*Evolutionary theory on sexual strategies*	*Cognitive developmental theories on the development of gender role*	*Social learning and observational learning theories of gender role*	*Bronfenbrenner's ecological theory on sex or gender role*
Summaries of theories or factors/comparisons: is sex or gender role development more likely to be	Sex is binary most of the time and is biologically determined	Reproduction is of particular importance because it determines what traits can be passed to the offspring. Men and women pose different challenges and economic tradeoffs to reproduce, leading to different 'selected' sexual behaviors and strategies	Children gradually understand that gender is stable by attaining gender stability and constancy as they grow up	Gender roles are learned by imitating others for the appropriate gender roles and behaviors. While children are prewired to imitate whatever comes to their attention, rewards and punishments may moderate whether the learning is successful	The bidirectional influences between individuals' characteristics and the different environmental contexts (in terms of different systems) surrounding individuals determines one's sex or gender role
Inborn or environmental influence?	More likely to be inborn. Biological factors potentiate individuals to behave	Most likely to be inborn, as certain gender roles are inherited across generations	More likely to be environmental. Children understand gendered behaviors differently in different environments	Most likely to be environmental. Children receive different rewards or punishments for gender-appropriate behavior in different environments	Both inborn and environmental. Both individuals' characteristics and environmental input affect sex or gender role development
Active (individuals can control it) or passive (individuals cannot control it)?	Passive, one cannot control the inborn sex but gender	More likely to be passive, as the 'selected' sex roles are mostly inherited	Both active and passive. Children's understanding of gender depends on their cognitive development. Children can actively seek for cognitive maturation but it is also passively determined by the biological maturation of their brains	Both active and passive. Children actively seek for behavior that leads to rewards, but they cannot control their environment in terms of what behavior is rewarded or punished	Both active and passive. It is relatively difficult to change the outermost system such as the macrosystem (i.e., culture). Nevertheless, individuals may also actively affect the systems around them. For instance, gender equality movement starts with several pioneers in striving for gender equality, which gradually affects other systems
Similar or different (different individuals show similar patterns or different patterns?)	More likely to be similar, as genetic or biological factors tend to be more universal	Similar but different. Gender difference from evolutionary theory was observed in nations of low sexual parity. The difference declined as the gender inequality gap decreased	Similar but different. Progress of brain maturation tends to be universal, but environmental influence on the understanding of gender roles is different	More likely to be different. Based on different experience (positive or negative) that individuals receive environmentally, individuals develop different gender roles	More likely to be different. Different cultures and socioeconomic contexts determine sex or gender role development differently

'contexts' surrounding individuals and affect their life span development. Starting with the slight biological differences between the two sexes such as sex-typed behavior that can be found in infants, sex roles are further reinforced and strengthened through the microsystem, mesosystem, exosystem, and macrosystem. Microsystem is the innermost circle surrounding individuals. Closed family members, teachers, and peers belong to microsystem. Families, peers, and teachers reinforce and strengthen the appropriate gender behavior and gender roles of children. Mesosystem refers to the interactions between microsystems. For instance, both parents and teachers tend to undermine girls' math and science abilities, which in turn strengthens the preexisting gender stereotype that girls do less well than boys. Exosystem means the socioeconomic context, such as media, neighborhood, and legal or social welfare services that are available in ones' social settings; it also involves the links between social settings. For instance, mass media impacts individuals on the ideologies about males and females. Children's experience and perceptions about gender role may also be influenced by the working status of mothers. Women are more likely to go out to work if there are suitable social contexts that provide educational opportunities and childcare services that encourage them to work; this indirectly affects the experience of children with working mothers. For instance, daughters of working mothers aspire for career more (e.g., Hoffman, 1998). Macrosystem, which is the outermost layer of Bronfenbrenner's model, refers to social and cultural ideologies that one is exposed to. For instance, some Chinese societies may still endorse the traditional Confucian beliefs about gender roles. Sayings such as *zoi gaa cung fu*; *ceot gaa cung fu*; *lou loi cung zi* (girls should submit to their fathers; wives should submit to their husbands; mothers should submit to their sons in later years, respectively) and *neoi zi mou coi bin si dak* (ignorance is a girl's virtue) are still commonly used. These cultural beliefs have been constantly strengthened and reinforced among Chinese for thousands of years, through families, media, schools' work settings, and so on. The pervasive effects of such beliefs have influenced the gender role perception of the Chinese for thousands of years, resulted in most Chinese women losing chances to receive education, and not being able to question the orders from men, which in turn reinforces the legitimacy of the dominating roles of men in families, job markets, politics, and ruling power. Summaries and comparisons of different theories concerning sex or gender role development are shown in **Table 1**.

Conclusion

In most cultural settings, men should be masculine, i.e., be aggressive, forceful, competent, dominant, and probably the bread winner, and women should be feminine, i.e., be soft, tender, caring, altruistic, and probably a mother. Such an ideology is presented in most cultural settings and is reinforced through the interconnections between the microsystem, mesosystem, exosystem, and macrosystem of the ecological theory (Bronfenbrenner, 1993)

Achieving and maintaining the culturally accepted manhood or womanhood, however, is not easy for both men and women. Vandello and Bosson (2013) argued that manhood is difficult to gain and is easily lost. To gain masculinity, men have to engage in masculine-typed activities such as risk taking and aggressive behavior, achieving in careers, and avoiding being feminine. They argued that maintaining manhood is a constant anxiety for men, as a single feminine act can destroy the masculine image being built and maintained for a long time. Vandello and Bosson (2013) concluded several studies on creating gender threat for males, and it has been found that males experience high level of anxiety and stress when they were asked to carry out feminine tasks. On the other hand, although womanhood or femininity has been viewed as more 'naturally' associated with females, Chrisler (2013) argued that womanhood is equally difficult to achieve. Womanhood is achieved through pursuing culturally accepted standard of beauty and being good mothers, which are also some big challenges that most females have to face.

Despite recent movements in reducing discrimination against individuals who hold different gender roles and gender identities (such as transgendered individuals) or sexual orientation (lesbian, gay, or bisexual individuals) by providing them equal rights in schools, work, communities, and laws, the traditional binary sex roles of femininity and masculinity still dominate the mainstream culture. "Gender role constraints oppress everyone, and we will all be better off if those constraints are loosened" (Chrisler, 2013: p. 119). It is hard to live a life completely free of gender roles or constraints, nevertheless. It is suggested that more efforts can be placed in 'neutralizing' the effects of gender roles in schools and mass media by not emphasizing the difference between males and females. After all, biology gives two sexes, gender does not necessarily have to be binary, and we can think, behave, and live in being feminine, masculine, androgynous, or completely 'genderless'.

Sex Selective Abortion

Daniel Goodkind, Independent Researcher, Arlington, VA, USA

Abstract

Sex selective abortion refers to the decision to terminate a pregnancy based on the sex of the fetus. In societies that have son preference, sex selective abortion is used more commonly after a fetus is found to be female (rather than male), which often results in a sex ratio at birth that is excessively masculine. Several societies have evinced rising sex ratios at birth in recent decades. This article reviews the factors that contribute to sex selective abortion and describes the major demographic and social characteristics of parents who use it. This article also discusses the dynamics of sex discrimination across the life course as well as possible future implications of sex imbalances among adults.

Introduction

Advances in prenatal testing technologies in recent decades have allowed parents to identify the sex of a fetus at an early stage of pregnancy. Sex selective abortion refers to the decision to terminate a pregnancy based on the sex of the fetus. In societies that have son preference, sex selective abortion is used more commonly after a fetus is found to be female (rather than male), which often results in a sex ratio at birth that is excessively masculine. Those distorted sex ratios are then carried forward as these birth cohorts enter young adulthood.

Several societies have evinced rising sex ratios at birth in recent decades. The earliest examples were noted in East Asia during the late 1980s and early 1990s (Gu and Roy, 1995; Goodkind, 1995), although since then such distortions have been observed in parts of South Asia and West Asia (Attané and Guilmoto, 2007; UNFPA, 2012).

This article reviews some of the broad factors that contribute to sex selective abortion. It also notes other factors that may also contribute to sex ratio variation even in the absence of sex selection. This article then describes some demographic and social features of those exhibiting selective abortion, theories of discrimination within the life course, and possible future patterns and implications that might be expected.

Three Factors Contributing to Sex Selection

Researchers have identified three key factors that have led to sex selective abortion in several societies. These factors are listed below, each of which will be summarized in turn.

1. son preference – the desire for at least one son,
2. low or declining fertility – which reduces the chances of having at least one son, and
3. access to prenatal sex-testing technology (and abortion).

The first factor is son preference. In traditional societies, sons were often more valued by parents than daughters because sons provided greater benefits – either economic or social – to the family. This is particularly true in patrilineal societies, where brides tend to move in with grooms, which often implied that daughter's loyalties then belonged to her husband's family rather than her natal family. Thus, in traditional societies, having many sons may be equated with wealth. That said, since sex selective abortion tends to occur at low levels of fertility, a more appropriate way of describing son preference is that parents want to have at least one son.

The second factor is declining fertility. When parents prefer to have fewer children, the number of slots available to have a son declines. Since the chances of having a son are just over 50% at each birth, at low levels of fertility, the concern for having a son at any given birth intensifies. Consider, for instance, that when parents have four children, only about 6% of families would not have a son by chance. However, when parents have only two children, about one-quarter of families would not have a son by chance. Prior research has suggested that 'replacement' levels of fertility (e.g., a total fertility rate, TFR, of 2.1 per woman), is a critical threshold for intensified concerns when parents desire at least one son. Yet at ever lower levels of fertility, the intensified concerns due to demographic change are typically counterbalanced by declining proportions of parents who want at least one son.

The third factor is access to both effective prenatal sex-testing technology as well as abortion services. Even if parents have son preference and their concerns for sons are intensified due to lower fertility, they cannot effectively choose the sex of their child in the absence of such technologies. Major advances in prenatal testing technologies around the 1980s (Bennett, 1983) allowed for the testing of fetal sex, and further advances permitted testing earlier within pregnancy, including within the first trimester. These advances have thus played perhaps the crucial role in the masculinization of sex ratios in many societies.

Other Sources of Variation in Sex Ratios at Birth

The 'normal' range of sex ratios at birth is generally considered to be anywhere between 103 and 107 male births per 100 females (Hill and Upchurch, 1995). The excess of male births is thought to reflect either the greater likelihood of male conceptions and/or the greater likelihood that male fetuses will survive during the prenatal period. Yet given that the range which is considered normal is fairly wide, even in the absence of prenatal testing technologies, other factors contribute to such variation. To cite just one example of variation within a particular society over time, Japan's sex ratio at birth gradually

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31038-8

rose from about 104 in the earlier twentieth century to a peak above 107 in the mid-1960s, only to fall back closer to 105 more recently. The 1960s peak occurred well before reliable prenatal testing is thought to have existed.

Among the many theories proposed to explain such variation are biological ones, such as genetics and maternal age. Broader environmental or behavioral explanations include the timing of coitus within the menstrual cycle, diet, and even altitude. Of course, the evidence underlying some of these proposed theories may reflect statistical or reporting biases. For instance, ratios tend to have large statistical variation. A sample of 10 000 or more births may be required in order to draw valid conclusions about sex ratio differences. Similarly, among possible reporting biases, some societies may underreport female births and children more than male births and children (Goodkind, 2011). An additional consideration, in cases of interracial marriages the ethnic identification of the child may be different depending on whether it is a son or daughter. An appendix is included which summarizes the wide variety of explanations proposed for variations in the sex ratio at birth – no attempt is made here to assess the validity of each one.

Areas Where Sex Ratios Have Risen and Basic Trends

The demographic outcomes of sex selective abortion first became apparent in Asia during the 1980s, most notably in South Korea, where the sex ratio at birth rose from around 106–107 in the mid-1980s to a peak above 115 in the early 1990s (Gu and Roy, 1995). Since the 1990s, China (Goodkind, 2011) and India, the world's two population billionaires, joined this group. This was not surprising to many observers, given strong patrilineal patterns in these societies, as well as the three contributing factors noted early. Less expected were other Eurasian countries that have evinced sex imbalances, such as group, such as Armenia, Azerbaijan, and Georgia. What was surprising about the latter group is that they were not widely known for having strong son preference.

In son-preferring societies, sex ratios at birth differ sharply depending on birth order, as well as the sex distribution of earlier births. The likelihood of sex selection rises dramatically if a daughter is born first. Typically, sex ratios of first births are normal, while second and higher order births then show more distorted ratio. This is because, as mentioned earlier, parents want at least one son and within a smaller family size and may only go beyond their ideal number if they have yet to have a son. There is also evidence of sex selection against male fetuses – some parents may want not only at least one son but also at least one daughter. For parents wanting at least one daughter, after the birth of one or two sons, the sex ratio of the next child may be excessively feminine.

Recently, however, in their most recent censuses, both Vietnam (in 2009) and China (in 2010) showed a notable elevation in the sex ratio of first births. Given the prior evidence that sex selection is limited to second and higher order births, this has come as a surprise. Why the very recent change? One likely explanation concerns the crisscrossing social forces identified earlier. As fertility declines, intensified concerns over reduced slots for having a son are usually counterbalanced by a decline in son preference overall, yet if some proportion of son-preferring parents now truly want only one child, sex selection will occur for the first birth. China's one-child policy would not appear to explain this very recent trend, since that policy had been in place for three decades without any appreciable increase in the sex ratios of first births.

The Substitution Hypothesis and the Role of Technology

Historical studies have documented evidence of both son preference and daughter discrimination in traditional societies that lacked access to prenatal testing technologies. Discrimination in such societies could be manifested through excess mortality of female infants or children (or even female infanticide). One key question is whether sex selective abortion simply adds to these ongoing traditional forms of discrimination or whether its use 'substitutes' for them and thus leads them to decrease. Comparisons of aggregate sex ratio measures of prenatal and postnatal discrimination over time suggest the possibility of both dynamics, but are inconclusive (Goodkind, 1995). As for survey data among individuals, some support for substitution has been found in Taiwan (Lin et al., 2014).

That said, advocates of abortion rights often argue that strategic substitution by parents does exist (Goodkind, 1999), and nearly all researchers seem to agree with a weaker formulation of the substation hypothesis – that prenatal sex-testing technologies have allowed parents to focus their concerns about the sex composition of children during the prenatal period. This weaker formulation may also shed light on the role of technology on son preference. As mentioned earlier, societies such as Azerbaijan and Armenia have recently exhibited large distortions in sex ratios at birth, yet neither society was well known in the past for son preference. It is possible, then, that prenatal sex-testing technologies have made sex discrimination in family formation acceptable in areas where traditional forms of discrimination (e.g., female infanticide) had not been.

Future Trends

For societies exhibiting sex selection, a variety of future trends in the sex ratio at birth have been considered (Attané and Guilmoto, 2007):

1. They continue to rise.
2. They rise, yet thereafter return to normal, as in the case of South Korea.
3. They remain at their current elevated levels.
4. The fall, yet not back to normal levels.
5. They oscillate back and forth.

Although it is too early to tell for sure, empirical evidence suggests that first scenario is unlikely. Sex ratios tend to reach a peak, after which they fall back, although perhaps not back to normal. Different societies may exhibit different patterns.

The Bachelors

We conclude by considering the future. Whether or not sex ratios at birth return to normal, what are some of the possible

social outcomes in societies where child sex ratios have become increasingly masculine? We consider below some of these possible outcomes, many have of which have been well identified (Gutentag and Secord, 1983; Hudson and den Boer, 2004). Although some of these possible outcomes are hotly contested, one outcome is certain – as child cohorts with large sex imbalances mature, there will eventually be large sex imbalances among young adults.

Perhaps the most discussed outcome of sex imbalances involves marriage squeeze. When excessively masculine birth cohorts reach the age of marriage, larger proportions of males will marry at later ages, or not at all. Moreover, in societies where females tend to marry males of a higher social status, it is poor men who will suffer most, since there will be few who are beneath them. Of course, the famine for males is a potential feast for females. And the effect on female marriage patterns is not at all certain. Although a wide selection of husbands could encourage women to marry at younger ages, if they are spoiled for choice and/or want to focus on career options, they may decide to marry at later ages. Marriage squeeze will become a major research topic in coming decades. South Korea was the first country to show substantial distortions in sex ratios at birth by the late 1980s, and distorted birth cohorts should be reaching peak ages of marriage from now until about 2025.

Another possible outcome is that large cohorts of bachelors will bring about increased crime and/or violence. Several researchers suggest that this has already happened (Edlund et al., 2007), although explanation for such findings may have nothing to do with the frustration of young men unable to find a bride (or romantic female partner). Any rise in crime or violence might simply be due to the shifting composition of the population. If young males tend to behave badly (compared to young females) and are more likely to commit crimes, then larger proportions of young males in any society will result in more crime per capita.

Yet one cannot rule out that sex imbalances among adults could have profound social consequences. Consider, for instance, voting. In many societies, voting patterns among women tend to differ compared to men. Thus, to the extent that societies have voting rights, a larger proportion of males in the population could swing elections and referendums in favor of whatever males tend to prefer. And if males are more likely to favor, say, military interventions, then military interventions could be more likely.

Appendix – Summary of Proposed Explanations for Variations in Sex Ratios at Birth

- Biological
  - genes (including possible ethnic differences),
  - maternal age and/or prior children born, and
  - differential benefits by sex of improvements in maternal and fetal health
- Environmental/behavioral
  - altitude,
  - diet, and
  - timing of coitus within the menstrual cycle
- Statistical/reporting
  - small sample size,
  - sex-based differences in reporting completeness (e.g., still birth by sex), and
  - sex differences in identification in multiethnic societies (includes 'minority status' hypothesis).
- Sex selection
  - preconceptive sperm sorting,
  - prenatal testing followed by sex selective abortion, and
  - policies that affect use or outcomes of sex selection.

Abstract

Psychological interventions, which have become known as sex therapy, have been designed to reverse the symptoms of sexual dysfunction. The research of Masters and Johnson inspired many approaches to sexual problems. Their main focus in therapy is on adequate sexual stimulation and the prevention of fear of failure and performance anxiety. Most of the evidence for the efficacy of sex therapy was produced 20 years ago. A recent meta-analysis failed to show robust evidence-based practice, except for female desire and female orgasmic disorder.

Introduction

Sex therapy is an approach to the treatment of sexual problems. Results of psychophysiological studies of sexual responses in sexually functional subjects in the 1960s allowed gynecologist William Masters and psychologist Virginia Johnson to develop a therapeutic format for the treatment of sexual inadequacy (1970). In this format, sexual problems were openly discussed, there was no time-consuming delving-into-past conflicts, and there were suggestions for a direct reversal of symptoms of sexual failure. Masters and Johnson preferred working with couples, because the interaction within the couple often contributes in important ways to the sexual difficulties. Other therapists have offered treatment to individuals and to groups of individuals or couples. Several other approaches developed from behavior therapy and rational emotive therapy and focused on performance anxiety and fear of failure. Others used interventions from couple and group therapy (Balon and Segraves, 2005; Leiblum, 2007). It is fair to say that nowadays almost all approaches to sexual difficulties incorporate elements from the Masters and Johnson sex therapy format.

Apart from organic causes, sexual problems may be attributed to interpersonal difficulties and to problems with emotional functioning. Masters and Johnson were convinced that 'adequate' stimulation would result in sexual response in an engaged partner. Adequate stimulation feels good, is rewarding, and facilitates focus of attention on those feelings. Originally, adequate stimulation in therapies was restricted to behaviors comprising the classical heterosexual foreplay, coitus, and orgasm sequence (Masters and Johnson, 1964). This criterion for adequate stimulation has been abandoned because of the rich diversity in sexual practices that exist in the real world.

Masters and Johnson hypothesized that fear of failure, and as a consequence becoming a spectator of one's own feelings, is the most important cause for sexual inadequacy. They devised a very ingenious procedure to assist people in becoming engaged in feelings of sexual excitement. Three important steps were specified. In the first step, people learn to accept that mutual touching feels good. In this step, demands for sexual performance, and anxieties related to such demands, are precluded by an instruction not to touch genitals or secondary sex characteristics (e.g., breasts). When the first step leads to acceptance of positive bodily feelings, the second step demands including genitals and breasts in mutual touching and caressing. Masters and Johnson have suggested some variations to accommodate specific sexual problems (e.g., premature ejaculation, erectile problems). The second step has to result in the physiological signs of sexual excitement – vaginal lubrication in women and erection of the penis in men. In the classical sequence, the first and second steps prepared for the third step, which consisted of coital positions, again with variations, and stimulation through coitus to orgasm. Although coitus may be relevant from a reproductive point of view, it is not always and certainly not the only way to experience the ultimate pleasures of sex (Laumann et al., 1999).

Desire, Excitement, and Orgasm

Masters and Johnson, on the basis of their psychophysiological studies, proposed a model of sexual response consisting of three phases: an excitement phase, an orgasm phase, and a resolution phase (Masters and Johnson, 1964). The excitement phase and orgasm phase may be recognized as the second and third step of the classic treatment format. When other therapists began to apply Masters and Johnson's format, it became clear that many patients do not easily engage in interactions prescribed by the sex therapy format. Apparently, an initial motivational step was missing. People who hesitate or avoid intimate interactions may lack desire, which often means that they do not expect the interaction to be rewarding. In 1979, Helen Kaplan proposed adding a desire phase, preceding the three phases specified by Masters and Johnson. Since Kaplan's proposal it has become clear that the prevalence of lack of desire is considerable (Kaplan, 1995). With hindsight, most people accept that lack of desire must be the most important sexual problem. It is a problem for the individual who does not arouse desire in his or her partner. In most instances, not feeling desire is in itself unproblematic, but lack of sexual desire may become a problem in the relationship.

Sex therapy was a fresh and new treatment. Sexual problems were openly discussed, there was no time-consuming delving-into-past conflicts, and there were suggestions for a direct reversal of symptoms of sexual failure. Masters and Johnson preferred working with couples because the interaction within the couple often contributes in important ways to the sexual difficulties. Other therapists have offered treatment to individuals and to groups of individuals or couples.

An alternative to Masters and Johnson's therapy format is the mimicking of normal sexual development through the use of masturbation (Heiman et al., 1976). This has been an important step for many women, especially those who missed this aspect of discovery of their own sexuality. In this approach, people learn to induce sexual excitement through masturbation to eventually apply this 'skill' in interaction with a partner.

Some approaches developed from cognitive behavioral therapy and rational emotive therapy focused on performance anxiety and fear of failure. Others used interventions from couple and group therapy. It is fair to say that nowadays almost all approaches to sexual difficulties incorporate elements from the Masters and Johnson sex therapy format.

Sexual Dysfunctions in Men

Diagnostic Procedures

The aim of the initial clinical interview is to gather detailed information concerning current sexual functioning, onset of the sexual complaint, and the context in which the difficulty occurred. This information gathering may be aided by the use of a structured interview and paper-and-pencil measures regarding sexual history and functioning. An individual and conjoint partner interview, if possible, can provide additional relationship information and can corroborate data provided by the patient. The initial clinical interview should help the clinician in formulating the problem. It is important to seek the patient's agreement with the therapist's formulation of the problem. When such a formulation is agreed upon, the problem may guide further diagnostic procedures.

Many men with erectile dysfunction may be wary of psychological causes of their problem. Psychological causes seem to imply that the man himself is responsible for his problem. This may add to the threat to his male identity that he is already experiencing by not being able to function sexually. Considering the way a man may experience his problem, it can be expected that it will not be easy to explain to him the contribution of psychological factors. A clinician knowledgeable in biopsychosocial aspects of sexual functioning should be able to discuss the problem openly with the patient. Dysfunctional performance is meaningful performance in the sense that misinformation, emotional states, and obsessive concerns about performance provide information about the patient's 'theory' of sexual functioning. When contrasting this information with what is known about variations in adequate sexual functioning, it is often clear that one cannot but predict that the patient must fail. For the clinician, a problem arises when, even with adequate stimulation and adequate processing of stimulus information according to the clinician's judgment, no response results, either at a physiological or a psychological level (Janssen and Everaerd, 1993).

At this point, a number of assessment methods aimed at identifying different components or mechanisms of sexual functioning may be considered. In principle, two main strategies may be followed: In the first, although a psychological factor interfering with response cannot be inferred from the report of the patient, one can still suspect some psychological factor to be at work. Possibly, the patient is not aware of this factor, thus he cannot report on it. Eliminating this psychological influence may result in adequate response. The second strategy applies when even with adequate (psychological) stimulation and processing, responding is prevented by physiological dysfunction. Physiological assessment may then aid in arriving at a diagnostic conclusion. The biopsychosocial approach predicts that it is inadequate to choose one of these strategies exclusively. The fact that sexual functioning is always psychophysiological functioning means that there may always be an unforeseen psychological or biological factor.

Psychological Treatments of Sexual Dysfunctions in Men

Approaches to Treatment

The most important transformation of the treatment of sexual dysfunctions occurred after the publication of Masters and Johnson's (1970) *Human Sexual Inadequacy*. First of all, they brought sex into the treatment of sexual problems. Before the publication of their seminal book, sexual problems were conceived as consequences of (nonsexual) psychological conflicts, immaturity, and relational conflicts. In most therapies for sexual problems, sex was not a topic in the therapeutic transactions. There were always things 'underlying', 'behind,' and 'besides' the sexual symptoms that deserved discussion. Masters and Johnson proposed to attempt directly to reverse the sexual dysfunction by a kind of graded practice and focus on sexual feelings. If sexual arousal depends directly on sexual stimulation, that very stimulation should be the topic of discussion. Here the second important transformation occurred: A sexual dysfunction was no longer something pertaining to an individual; rather, it was regarded as a dysfunction of the couple. It was assumed they did not communicate in a way that allowed sexual arousal to occur when they intend to 'produce' it. Masters and Johnson thus initially considered the couple as the 'problem' unit. Treatment goals were associated with the couple concept: The treatment goal was orgasm through coital stimulation. This connection between treatment format and goals was lost once Masters and Johnson's concept was used in common therapeutic practice. People came in for treatment as individuals. Male orgasm through coitus adequately fulfills reproductive goals, but it is not very satisfactory for many women because they do not easily achieve orgasm through coitus. What have remained over the years, since 1970, are a direct focus on dysfunctional sex and a focus on sexual sensations and feelings as a vehicle for reversal of the dysfunction.

What Masters and Johnson tried to achieve in their treatment model is a shift in their patients' focus of attention. Let us look at one of Masters and Johnson's interventions to elucidate this point. People with sexual dysfunctions tend to wait and look for the occurrence of feelings, instead of feeling what occurs – hence, the spectator role. Their attention is directed toward something that is not there or does not exist, which is frustrating. In simplest form, Masters and Johnson propose to redirect attention by using the following steps: first of all they manipulate expectations by instructing the patient about what is allowed to occur and what is not. It is explained to the patient that nonsexual feelings are to be accepted as a way to accept sexual feelings later on, and therefore sexual areas are excluded

in the initial homework tasks. From a psychological point of view, this manipulation is ingenious; it directs attention away from sex – when you feel a caress on your arm it may be pleasant but (now) it is not sexual – however, at the same time, it defines sexual feelings as feelings in 'sexual areas.'

To attain a direct approach of sexual function, numerous variants of couple, communication, and group therapy have been used. Rational emotive therapy has been used to change expectation and emotions. To remedy biographical memories connected with sexual dysfunction, psychoanalytic approaches have been used as well as cognitive behavior therapy approaches. There are specific interventions for some dysfunctions; for example, premature ejaculation has been treated with attempts at heightening the threshold for ejaculatory release (stop–start or squeeze techniques) (Balon and Segraves, 2005; Leiblum, 2007; Kolodny et al., 1979).

Recently, as a spin-off of research into cardiac vascular smooth muscle pharmacology, drugs have become available which act by relaxing smooth muscles in the spongiose and cavernous structures in the penis. This relaxation is necessary to allow blood flow into the penis, thus causing an erection. Some of these drugs (e.g., sildenafil – Viagra®) support the natural neurophysiological reaction to sexual stimuli. Others act locally in the penis without sexual stimulation. To slow down speed of ejaculation in men with premature ejaculation, serotonin selective reuptake inhibitors (SSRIs) seem to be helpful (Waldinger et al., 1998).

Smooth muscle relaxants like sildenafil are helpful in older men when less naturally occurring transmitters are available. Men with vascular or neurodegenerative diseases (e.g., diabetes, multiple sclerosis) may also benefit from the use of smooth muscle relaxants (Boolell et al., 1996). Although these drugs are very effective, they do not help every man with erectile problems.

Pharmacological treatment for erectile disorder may be an important step in restoring sexual function (Shamloul and Ghanem, 2013). Most couples will need information and advice to understand what they may expect from this treatment. For many, it will not bring the final resolution of their relationship problems. In addition to drug treatment, they will need some form of sex therapy or psychotherapy.

Validated Treatments for Male Sexual Dysfunctions

It has been difficult to get an overview of treatments for sexual dysfunctions because any proposal about how to approach dysfunctions was valid. This has changed through the introduction of criteria for validated or evidence-based practice by the American Psychological Association (APA Presidential Task Force on Evidence-Based Practice, 2006). From a systematic review and meta-analysis of psychotherapies for male sexual dysfunctions, it appears that the state-of-the-art is far from satisfactory (Frühauf et al., 2013). Randomized controlled trials (RCTs) did not show clear evidence for Erectile Dysfunction and Premature Ejaculation. Male Dyspareunia and Male Orgasmic Disorder were never studied in RCTs. Berner and Günzler (2012), although less strict about inclusion of studies, were more optimistic about the efficacy of interventions. Although the evidence-based practice movement should be firmly supported, unqualified support would be disastrous for the practice of the treatment of sexual problems. The care for patients with sexual problems must be continued even without proof according to the rules of 'good clinical practice.' The sensible clinician will learn to be very careful about any claims concerning either diagnostic procedures or treatments, and should support the science that is the background for her or his actions.

Sexual Dysfunctions in Women

Diagnostic Methods

Similar to the procedures in men, initial interviews should help the clinician in formulating the problem and in deciding whether sex therapy is indicated. Since sexual problems can be a consequence of sexual trauma, it is necessary to ask if the woman ever experienced sexual abuse. An important issue is the agreement between therapist and patient about the formulation of the problem and the nature of the treatment. To reach a decision to accept treatment, the patient needs to be properly informed about what the diagnosis and the treatment involve and what is known about the efficacy of the proposed therapy. Depending on the nature of the complaint, the initial interviews may be followed by medical assessments. In contrast to the assessment of men, the psychobiological assessment of women's sexual problems is not well developed (Laan and Everaerd,1995).

Psychological Treatments of Sexual Dysfunctions in Women

Approaches to Treatment

Similar to men, the treatment of sexual dysfunction in women contains many elements from Masters and Johnson sex therapy. As noted before, an important addition, especially in women, is the use of masturbation to discover their own sexuality.

Low sexual desire is generally treated with sensate focus exercises to minimize performance pressure, and communication training. In the treatment of sexual aversion, the focus is on decreasing anxiety, the common core of sexual aversions. Behavioral techniques, like exposure, are most commonly used.

Treatment of sexual arousal disorder generally consists of sensate focus exercises and masturbation training, with the emphasis on becoming more self-focused and assertive in asking for adequate stimulation (Masters and Johnson, 1970).

For the treatment of primary (lifelong) anorgasmia there exists a well-described treatment protocol (Heiman et al., 1976). Basic elements of this program are education, self-exploration and body awareness, and directed masturbation. Because of the broad range of problems behind the diagnosis of secondary (not lifelong) and situational anorgasmia, there is no major treatment strategy for this sexual disorder. Depending on the problem, education, disinhibition strategies, and assertiveness training are used (see Frühauf et al., 2013). It is important to identify unrealistic goals for treatment like achieving orgasm during intercourse without clitoral stimulation.

For dyspareunia (genital pain often associated with intercourse), there are multiple possible somatic and psychological causes. A common picture is vulvar vestibulitis, pain at small inflamed spots at the lower side of the vaginal opening. However, often there is no clear organic cause for the pain.

Treatment should be tuned to the specific causes diagnosed and can vary from patient to patient. Behavioral interventions typically include prohibition of intercourse, finger exploration of the vagina, first by the woman, then by her partner. Sensate-focus exercises may be used to increase sexual arousal and sexual satisfaction. Pelvic floor muscle exercises and relaxation training can be recommended in case of vaginismus or a high level of muscle tension in the pelvic floor.

Treatment of vaginismus commonly involves exposure to vaginal penetration by using dilators of increasing size or the women's fingers. Pelvic floor muscle exercises may be used to provide training in discrimination of vaginal muscle contraction and relaxation, and to teach voluntary control over muscle spasm.

Pharmacological treatment of sexual disorders of women is just beginning. Smooth muscle relaxants have been used in women to ameliorate sexual arousal and as a consequence hypoactive sexual desire. It appears that drugs like sildenafil produce smooth muscle relaxation and increased genital blood flow, but they have no effect on the subjective experience of sexual response. In women with subphysiological levels of testosterone – mainly in the postmenopause – testosterone patches appear to have an effect on mood, energy, and libido.

Validated Treatments for Women's Sexual Dysfunctions

Reviews of treatments for sexual dysfunctions in women following the criteria for validated or evidence-based practice have been published (Heiman and Meston, 1997; Baucom et al., 1998; Günzler and Berner, 2012; Frühauf et al., 2013). Heiman and Meston conclude that treatments for primary anorgasmia fulfill the criteria of 'well-established,' and secondary anorgasmia studies fall into the 'probably efficacious' group. They conclude with some reservations that vaginismus appears to be successfully treated if repeated practice with vaginal dilators is included in the treatment. Their reservations are due to a lack of controlled or treatment comparison studies of vaginismus. All authors conclude that adequate data on the treatment of sexual desire disorder, sexual arousal disorder, and dyspareunia are lacking. Frühauf et al. (2013) endorse the conclusions of Heiman and Meston and note that "according to our results the situation has not changed much" (p. 929).

Although the evidence-based practice movement deserves support, care for patients with sexual problems must be continued even without proof according to the rules of 'good clinical practice.'

Future Directions

Sex therapy bloomed in the 1970s and 1980s, but reviews of evidence-based treatments suggest that developments stagnated and very few new studies have been undertaken. The recent shift to biological approaches will continue, at least for a while. Viagra and testosterone patches will shortly be followed by more centrally acting drugs (e.g., dopamine agonists). The search for drugs has provoked a wide range of studies into the biological basis of sexual function. This work inspires behavioral and cognitive neuroscience studies, which may provide a framework and new tools to better understand sexual emotions and sexual motivation.

Sexism

Fabio Lorenzi-Cioldi and Clara Kulich, Faculty of Psychology and Educational Sciences, University of Geneva, Geneva, Switzerland

Abstract

This article first reviews the historical rise and the developments of psychological research on sexism which led to the differentiation between biological sex and cultural gender, and highlights commonalities between gender relations and other status-based intergroup relations. Old-fashioned, overt and explicit forms of sexism are then distinguished from contemporary, more subtle, and implicit forms. The latter are characterized by ambivalence of hostility and benevolence toward women. The final section discusses major behavioral consequences of the different forms of sexism, emphasizing the harmful impact of benevolence on women's feelings of self-worth and competence, and actual performances.

Introduction

Historical Roots: The 'Discovery' of Sexism

Unequal treatment of individuals based on their sex is probably as old as humankind. However, the social recognition that unequal treatment is discriminatory, and the ensuing notion of 'sexism,' is far more recent. Long before gender inequality was recognized as a societal problem, early feminists such as Christine de Pizan in the fifteenth century in France, Mary Wollstonecraft in the seventeenth century in Britain, and more recently Simone de Beauvoir, only to name a few, denounced the arbitrariness and the illegitimacy of the hierarchical organization of gender differences in society. But it was not until a speech on 'Women and the undergraduate' by Pauline M. Leet at an US university in 1965 that the term sexism entered lay people's vocabulary, and became a matter of debates. Leet explained this notion by establishing a parallel with racism, a construct that people were already familiar with:

> When you argue … that since fewer women write good poetry this justifies their total exclusion, you are taking a position analogous to that of the racist — I might call you in this case a 'sexist' … Both the racist and the sexist are acting as if all that has happened had never happened, and both of them are making decisions and coming to conclusions about someone's value by referring to factors which are in both cases irrelevant.
>
> p. 3: quoted in Shapiro, 1985: p. 6

Sexism is a form of prejudice or discriminatory treatment based on a person's sex. The coinage of this term occurred in concomitance with the realization that the persistent social disadvantage of women urged a collective response. Until World War Two, the term 'minority' typically referred to the numerical inferiority of national and linguistic groups. Only in the 1950s its meaning made a significant shift to label groups that are inferior in status, or are stigmatized, such as women, people with disabilities, or the elder. Since then, the notion of minority has become "a general term for all groups subjected to prejudice and discrimination" (Meyers, 1984: p. 1). This was also a starting point for the study of prejudice (e.g., Allport, 1954) and its underlying motivations originating in intergroup relations (e.g., Tajfel, 1981).

When interest in studying sex differences began to grow, sexist ideology was embedded in the questions asked. Society and researchers until the beginning of the twentieth century assumed that physiological and biological characteristics such as males' bigger brain size and physical strength were evidence of men's superiority. Early research used such characteristics to examine their role in predicting intelligence. But extensive research by Terman and his collaborators could not show any evidence of consistent differences in intelligence between men and women, which resulted in the revision of intelligence tests based on this assumption (Terman and Merrill, 1937). Many subsequent empirical studies indulged in identifying and quantifying sex differences in behavior and personality. These efforts were summarized and interpreted by Maccoby and Jacklin in their authoritative book *The Psychology of Sex Differences* (1974). Their comprehensive summary of the literature led them to conclude that most beliefs about existing sex differences, such as 'girls are more sociable than boys' or 'boys are better at cognitive tasks,' were not supported by empirical research. Overall, this research showed more similarities than differences between the sexes. Maccoby and Jacklin, nonetheless, acknowledged the existence of specific differences such as men's superiority in math and spatial aptitudes, and women's superiority in verbal tasks. However, instead of advocating causes related to innate characteristics of the sexes, they suggested that such differences could be adequately accounted for by socialization processes and stereotypes about women and men. As a consequence, further research in the social sciences began to focus on learning processes, rather than biological sex, as factors influencing the observed sex differences.

Maccoby and Jacklin's work was criticized due to its narrative approach. It was not until recently that Hyde (2005) conducted a more sophisticated analysis of this past and the subsequent literature. Despite the use of more rigorous meta-analytic methodologies, her analysis basically corroborated Maccoby and Jacklin's conclusions. The findings allowed for the conclusion that, overall, "Women and men are more alike than they are different" (p. 581), and that differences between the sexes are smaller than the differences that can be found within each sex. Though advocating a provocative *gender similarities hypothesis*, Hyde likewise mentioned exceptions, for instance motoric behaviors and sexuality, but most importantly differences in self-attributions of traits associated with

two key dimensions of stereotypes: *warmth* and *competence*. Women were shown to develop interdependent and relational self-construals, while men appeared to focus on independence and agency. As we know today, these differences derive from the gendered treatment of men and women. Contemporary research on sexism is highly influenced by the distinction between these two types of self-construals, and focuses on the negative consequences of applying them when distinguishing between men and women (e.g., Wood and Eagly, 2010).

The shift from biological approaches of sex differences to social and cultural ones urged a revision of concepts and terminology. Differences between men and women that could be accounted for by stable biological factors are since denoted with the term *sex*, while differences due to more malleable cultural factors are denoted with the term *gender*. An important discovery in empirical research was that social context moderates differences that were thought to be rooted in the biological sex, thus making the term gender more accurate. As Deaux and Major write "Now you see them, now you don't" (1987: p. 369), meaning that in certain contexts we observe differences in attitudes and behaviors between men and women, while in other contexts these differences vanish. A seminal experiment by Goldberg (1968) showed that evaluations of a piece of work (e.g., an article) varied as a function of the presentation of the author as female or male. Thus, it was not the actual competence of the article's author that led to perceptual and stable differences in the article's quality, but the observers' precognitions in the form of gender stereotypes. Although Goldberg's findings have suffered from a lack of replication, the idea of social context as an important moderator of sex differences crucially influenced the upcoming work.

The Social Status Dimension

In virtually all countries around the world, men are in socially dominant positions relative to women. From this observation, and drawing on the evidence of contextual effects on sex differences, most work on sexism has focused on the status differentials between men and women. It is of no surprise that the mere use of the term 'sexism' conveys the idea of discrimination against women, not men. Although there are incidences of sexism against men, that is *reverse sexism*, the consequences of gender discrimination are usually psychologically more harmful for the powerless. References to sexism against men are seldom. The *Ambivalence Toward Men Inventory* (Rudman and Glick, 2008) is one of the few attempts to measure sexist beliefs against men.

Despite differences between the gender status system and other long-term status systems, notably ethnicity, age, or social class, the study of status hierarchies has provided valuable insights for understanding how gender operates at a more general level (see Lorenzi-Cioldi, 2006; Ridgeway, 2011). The assumption that men have higher status and greater power than women is central to many social psychological analyses of sexism (Wood and Eagly, 2010). Stereotypic beliefs about men and women are firmly rooted in society's gendered division of labor, and therefore in the social structure (Guimond et al., 2013; Eagly, 1987). In general, less prestigious roles and occupational domains (e.g., nurse) ask for communal behavior, whereas more prestigious ones (e.g., bank trader) ask for agentic behavior. For instance, Johannesen and Eagly (2002) demonstrated that participants attribute higher scores of positive and negative agency to people, rather than communion, as a function of people's professional status. The diffuse knowledge that men and women are unevenly distributed in the occupational hierarchy boosts the belief that, in actuality, men *are* agentic and women *are* communal. Accordingly, perceivers come to believe that men and women possess the personality characteristics that are required to perform their respective social roles. Overall, then, the empirical evidence shows that men and women are attributed traits and characteristics deriving from implicit assumptions about their social status, overriding to a large extent the role of biological sex. In a seminal demonstration of this central hypothesis of *social role theory*, Eagly and Wood showed that, knowing only the gender of the protagonist of an influence scenario, participants inferred higher status for men than for women. In contrast, when both genders were portrayed in an ostensibly similar occupational role, the impact of gender stereotypes was reduced (see Eagly, 1987). Likewise, Lorenzi-Cioldi demonstrated this preeminence of status cues in the interpretation of male and female behavior in a study in which participants rated two managers and two employees of each sex on agentic and communal traits. Participants matched the traits according to the targets' professional roles, rather than their sex, judging both male and female managers as more agentic than the employees (see Guimond et al., 2013).

A host of analyses of secondary data provides further support to this social role hypothesis. To illustrate, Twenge (2001) examined assertiveness among women using survey data gathered from 1931 to 1993. She found that levels of this agentic personality trait varied according to historical periods, with higher levels corresponding to women's increased access to the labor market. Current societal trends toward more representative numbers of women in higher professional strata allow for the prediction that differences in judgments about men and women tend to fade away (see Diekman and Eagly, 2000). In particular, the greater variety of social roles enacted by women should be conducive to beliefs of an increased agency of women's personalities.

Types of Sexism

As we mentioned in the former section, sexist attitudes are rooted in gender stereotypes that ascribe higher status to men than to women. Thus, the concept and the measurement of sexism are largely concerned with gender asymmetries disadvantaging women. The contemporary literature lingers over a distinction between overt and more subtle forms of sexism. In what follows, we describe developments in the study of prejudice and stereotypes which will inform the understanding of the current construct and measures of sexism in the field of social psychology.

Evolution of Definitions of Prejudice

Early approaches considered prejudice as "an antipathy based upon a faulty and inflexible generalization" (Allport, 1954: p. 9). Prejudice was therefore intrinsically negative and hostile.

However, research showed that most social groups are also ascribed positive characteristics. For instance, Myrdal suggested, already in 1944, that contradicting norms expressed by the American Creed produced ambivalent attitudes about racial minorities. When people express negative prejudice, they tend to express at the same time sympathy, such as concerns for unjust treatment. Katz and his collaborators were the first to systematically investigate the effects of prejudice, sympathy, and the combination of the two (e.g., Katz and Hass, 1988).

The focus on the ambivalence of prejudice was further triggered by difficulties encountered in those days' techniques to measure prejudice. Such measures were explicit, typically asking people to associate traits to various social groups (e.g., aggressive, lazy, intelligent, etc.; see Katz and Braly, 1933). However, after World War Two people's sensitivity to minority issues increased. Egalitarianism became a social norm condemning the use of overt stereotypical generalizations based on group membership. Observations in the 1950s alluded to the fact that, at least in higher social classes, participants knew about the political correctness of egalitarian attitudes (McKee and Sherriffs, 1957). In concomitance with the feminist and antiracism movements in the 1970s, various types of *–isms* gained visibility and became blameworthy. As a consequence, the tendency to endorse overt prejudice against women declined over the years. Yet, in this process, more subtle forms of prejudice came into being, asking for a revision of the definition of this concept and of its measurement (see Maass et al., 2000). Such a revision was first met by Katz and Hass (1988), in the racial domain. In the gender domain, Guttentag and Secord (1983) advocated the necessity to take into account ambivalence arising from protective attitudes toward women. A few years later, Glick and Fiske (1996) presented the first psychometric scale integrating these principles (*Ambivalent Sexism Inventory*).

As a result of these developments, sexism, though still defined in terms of prejudice and discriminatory behavior, now includes combinations of *hostility* and *benevolence*. Accordingly, Glick and Hilt (2000) define prejudice as "*the implicit or explicit attitude that a group deserves inferior status*. The cognitive, emotional, and behavioral aspects of prejudiced attitudes may (for the prejudiced perceiver) be subjectively favorable, unfavorable, or ambivalent in their orientation toward the target group, yet they all serve to promote and maintain that group's subordination." (p. 245).

Ambivalence in Sexism

Early research on sex differences and stereotypes helps to understand the ambivalence of modern manifestations of sexism. The investigation of the content of gender stereotypes has its origin in Terman and Miles' work. Initially, these authors endeavored to examine sex differences in intelligence. But in their subsequent and most known work, *Sex and Personality* (1936), they took a different stand, conceding that research should rather focus on differences between male and female *temperaments*. In their *Test of Attitudes and Interests*, they assumed that masculinity and femininity are opposing ends of a single continuum, that this continuum is anchored in biology, and that temperaments can be assessed by asking men and women about their emotions, knowledge, and opinions. Deviations from the endorsement of the adequate masculine or feminine temperament were then considered as pathologies (i.e., indications of inversion and homosexuality, and of a variety of psychological maladjustments). Parsons and Bales (1955) likewise drew parallels between masculinity and instrumental roles in professions, and between femininity and expressive roles in the family, offering a broader sociological perspective on gender stereotypes. Broverman and collaborators later took up this idea in their *Questionnaire of Sex-Role Stereotypes* (Broverman et al., 1972). Their findings have long been considered as strong evidence for stereotypes portraying women as "less competent, less objective, and less logical than men," and men as "lacking interpersonal sensitivity, warmth, and expressiveness in comparison to women." (p. 75).

In the beginning of the 1970s, however, this one-dimensional (and bipolar) view of the masculinity–femininity construct began to be questioned. Bem and Spence empirically demonstrated that masculinity and femininity could be more adequately represented as two independent dimensions. As a consequence, the avenue was open for an individual to conceive of him/herself as possessing traits belonging to both personality types. With this notion of 'psychological androgyny' as a self-conception allowing for behavioral flexibility and better self-esteem, the simultaneous presence of masculine and feminine traits in each person, regardless of biological sex, was not considered abnormal anymore (see Lorenzi-Cioldi, 1996). Later conceptions of the androgynous person stressed the non-use of a gender-schema (Bem, 1981), supporting the ideal of a gender-blind society (i.e., *we are all the same*) endowed with the potential to overcome sexist attitudes and behaviors.

Let us turn to our initial question of how sexism is becoming increasingly ambivalent. Following the literature and their own investigations, Fiske, Glick, and their collaborators propose that *competence* and *warmth* are key dimensions of group stereotypes in their *stereotype content model* (Fiske et al., 2002). In what can be considered as an extension of Eagly's social role theory, they show that members of high-status groups are typically described as agentic (i.e., influential, independent, competent), while members of low-status groups are mainly described as communal (i.e., warm, caring, nurturing). Hence, this model implies that men and women are considered as complementing each other. But they are not equal. Men are attributed higher status, influence, and power, and receive respect for their agentic qualities, making them suitable candidates for leadership positions and other prestigious social roles. In contrast, women are praised for their interpersonal skills, which confer them positivity (see the so-called 'women are wonderful' effect; Wood and Eagly, 2010). But at the same time, this ostensible liking of women reveals a lack of agency, and thus competence, resulting in disrespect. In an apparent paradox, adulating women for their interpersonal skills undermines their evaluation in situations where competence is demanded. As a result, women are perceived to be suitable for low-status roles (e.g., domestic and health-care activities), and less suitable for high-status roles (e.g., decision-making positions). In sum, the positive connotation of the warmth dimension fuels ambivalence in a context where competence is relevant, and leads to the actual devaluation of women.

Glick and Fiske (1996) argue that the negative component of the stereotype is reflected in *hostile sexism*, and the positive one in *benevolent sexism*. A combination of the two produces ambivalence: The allegedly positive message communicated by benevolence masks the underlying hostile aim to dominate women and to keep women in their place. For example, research has shown that women may be applauded for their performances, yet resources are not allocated, or are even misattributed to others (Guinote and Vescio, 2010). Benevolent sexism expresses itself through protective paternalism, complementary gender differentiation, and heterosexual intimacy (Glick and Fiske, 1996). Protective and complementary aspects of benevolent sexism impact on the perception of women as needing protection and being unable to do things by themselves. Furthermore, they create expectations about the course of social interaction. On the one hand, men are expected to exert power over women, to protect, and to take care of them, putting them into a dependent position. On the other hand, women are compelled to assist this behavior by showing their affection and subordination to men. Indeed, research demonstrated that women perceive benevolent-sexist men as more attractive than hostile-sexist and nonsexist men (e.g., Montañés et al., 2013). Expectations of traditional gender roles, which figure men as protectors and women as *protégées*, should thus create the least conflict and the higher attraction between sexes. In line with this reasoning, experimental findings have shown that women face more difficulties to resist benevolent than hostile treatment (e.g., Becker and Wright, 2011). In addition, heterosexual interdependency and sexual attraction between men and women deepens the influence of such softer forms of prejudice in gender relations. The gender hierarchy is unlikely to be secured only through open hostility and subjugation. It is more efficiently maintained by coupling it with paternalism (Glick and Fiske, 1996; Rudman and Glick, 2008).

Hostile gender relations are learned and applied at an early age. Glick and Hilt (2000) offer a review of the literature on developmental aspects of sexism. At 9 months, children discriminate between male and female faces, and voices. At 2–3 years, they label themselves as boys or girls, and they know gender stereotypes related to objects (e.g., toys, clothes, and work). At kindergarten age, they become aware of power differences between genders, associating boys with power and negative traits (e.g., strong, fast, aggressive, cruel) and girls with fear, helplessness, and positive traits (e.g., needs help, nice, affectionate). This goes hand in hand with the development of negative attitudes toward, and dislike of, the other sex, and avoidance of interaction and play with the other sex (e.g., Maccoby and Jacklin, 1974). By the age of five, children have internalized that gender is a stable category. Accordingly, they begin to put emphasis on their gender identity, and engage in competitive forms of gender differentiation with the aim to show that the ingroup is better than the outgroup (Rudman and Glick, 2008). It is only with the rise of romantic sexual attraction, at about age 11, that gender relations become more complex and ambivalent, because positive emotions mix with the habitual hostility. According to correlational findings, romantic experiences are related to sexism, creating hostility against girls in adolescent girls and benevolence toward girls in adolescent boys (de Lemus et al., 2010). Glick and Hilt (2000) suggest that during puberty boys develop ambivalent feelings toward girls that include both hostility and benevolence. They direct benevolence toward girls who correspond to the feminine stereotype and whom they want to interact with, and hostility toward girls that do not comply with their expectations. In contrast, girls demonstrate awareness of status differences. They perceive higher power in boys, thus experiencing less satisfaction from interactions with boys. Consequently, they hold onto rather hostile attitudes toward boys. However, these attitudes can be undermined when girls enter a heterosexual relationship, which may produce ingroup hostility (de Lemus et al., 2010). Thus, adolescents enter the gender dynamics of adulthood where women are rewarded by men with benevolence when they behave in line with traditional gender roles.

Measuring Sexism

The acknowledgment that the negative effects of prejudice are not solely due to hostile attitudes and behaviors toward women, but can also derive from positive attitudes, was an important step in the development of sexism measures. Such measures can be roughly partitioned into two historical phases. The first phase focused on feminine and masculine personality traits which were supposed to fit biological sex. In the second phase, measures encompassed more explicit attitudes toward women. These measures were often used to generate hypotheses about discriminatory behavior toward women, or to relate them to other measures of social inequality.

First Phase

Following Terman and Miles' (1936) and Broverman et al.'s (1972) attempts to measure male and female temperaments and personalities, research produced much evidence about social attitudes toward the sexes. Jarrett and Sherriffs (1953) offered one of the initial attempts to assess, by means of a list of positive and negative behaviors, attitudes "toward the relative 'value' of men and women in our culture" (p. 41). The authors assumed that 17 of the items were stereotypically male (e.g., "Proportional to their numbers, most responsible for auto accidents in 1939 were ..."), 17 stereotypically female (e.g., "Having the most understanding for the needs of children are ..."), and 24 neutral. Participants judged for each item if it was true for men or for women. Results showed that, overall, participants gave more favorable scores to men compared to women. This finding points to the intriguing fact that both men and women show similar tendencies to value the higher-status group. The same authors conducted another study with similar items, and concluded that women and men hold the same stereotypes. Moreover, they were surprised to find that only 5 of the 24 presumably neutral items were actually judged as neutral. The conclusion was that most behavior is part of the male or female stereotype. In an attempt to overcome some methodological deficiencies of these studies, McKee and Sherriffs (1957) asked psychology students to rate men and women on a series of adjectives. Overall, men were again evaluated more favorably than women, an effect that was even stronger among women than men, suggesting a consensual ascription of legitimacy to the gender hierarchy.

Second Phase

This historical phase is divided up in three generations of sexism measures. The first aims to reveal the content of hostility toward women; the second aims to measure hostility in more indirect ways in order to meet social desirability concerns that make people hide prejudice; finally, the current generation integrates the dynamics of ambivalent sexism. We will only mention a few examples. An exhaustive summary of sexism measures is provided by Beere (1990).

First Generation – Old-Fashioned Attitude Scales

The 1970s and 1980s witnessed the publication of a number of well-designed gender attitudes scales. These scales were widely used and translated into different languages, which allowed for the first time a comprehensive test of their reliability and validity. They can be considered old fashioned because they measure traditional attitudes about gender roles and women's inferiority, notably in competence. Examples are Spence et al.'s *Attitudes Toward Women Scale* (AWS; e.g., "Women should be concerned with their duties of childbearing and house tending rather than with desires for professional or business careers"), Rombough and Ventimiglia's *Old-Fashioned Sexism Scale* (OFS; e.g., "Women should stay at home and care for the children"; "Men make better engineers than women"), and Beere et al.'s *Sex-Role Egalitarianism Scale*, with items assessing attitudes toward women and men in both traditional and nontraditional roles in various domains (marital, parental, employment, social, heterosexual, and educational).

Second Generation – Modern Sexism Scales

Gender stereotypes have been quite stable over time, and traditional expressions of hostile sexism in public discourse and sexual violence are still present in the twenty-first century. Nonetheless, in western societies, the restrictive nature of expectations about men's and women's social roles and behaviors has loosened up after the feminist movements of the 1970s and 1980s. Thus, more indirect ways of expressing sexism have become common. Two widely used instruments Tougas et al.'s *Neosexism Scale* and Swim et al.'s *Modern Sexism* Scale (MSS) illustrate this renewal. Indeed, these instruments tap opinions about egalitarian practices, rather than asking plain questions about women's competence or gender roles. Tougas et al. define neosexism as a "manifestation of a conflict between egalitarian values and residual negative feelings toward women" (1995: p. 843; e.g., "Women will make more progress by being patient and not pushing too hard for change"; "Due to social pressures, firms frequently have to hire underqualified women"). Likewise, subscales from the MSS deal with the *Denial of continuing discrimination* (e.g., "Discrimination against women is no longer a problem in the United States"), the *Antagonism toward women's demands* (e.g., "It is easy to understand the anger of women's groups in America"), and the *Resentment about special favors for women* (e.g., "Over the past few years, the government and news media have been showing more concern about the treatment of women than is warranted by women's actual experiences."). Nonetheless, MSS still includes measures of the traditional, more overt sexism (e.g., "Women are generally not as smart as men").

Third Generation – Ambivalence

The above scales still represent clearly negative statements, either overt or more subtle. None of these measures managed to integrate the ambivalent nature of modern prejudice that was initially called into attention by Guttentag and Secord (1983). This requirement was met by *ambivalent sexism theory* (Glick and Fiske, 1996). Central to this theory is the softer and friendlier type of sexism conveyed through benevolence. Traditional *hostile sexism* is characterized by its overtly negative nature that emphasizes women's inferiority to men, whereas *benevolent sexism* emphasizes status differences by affectionate and patronizing behaviors (Glick and Fiske, 1996; Rudman and Glick, 2008). Benevolent sexism is potentially equally harmful as the hostile, but through a different process. Its ostensibly flattering and friendly nature conceals the underlying expression of dominance, making it more likely to be accepted by women. Benevolent sexism meets social norms that demand that men protect women. It legitimizes status differences, and undermines potential conflicts and tensions.

Hostile and benevolent forms of sexism occur most often side by side. Indeed, benevolence contributes to mask the negativity of hostility (e.g., Barreto and Ellemers, 2013). Thus, the *Ambivalent Sexism Inventory* (Glick and Fiske, 1996) includes a *Hostile sexism* subscale (HS; e.g., "Many women are actually seeking special favors, such as hiring policies that favor them over men, under the guise of asking for 'equality'") and a *Benevolent sexism* subscale (BS). The latter has three subcomponents that correspond to the above-mentioned characteristics of benevolence: *Protective paternalism* (e.g., "Women should be cherished and protected by men"), *Complementary gender differentiation* (e.g., "Many women have a quality of purity that few men possess"), *and Heterosexual intimacy (*e.g., "*Men* are incomplete without women"). Across 16 nations, Rudman and Glick (2008) found HS and BS to be highly correlated. HS predicted negative trait ascriptions to women, and BS positive trait ascriptions, thus supporting the view of prejudice as an antipathy plus an affectionate patronizing component.

Collectively, the measures described so far can be considered as *explicit* measures of sexism. In concomitance with these measures, various scholars have argued that expression of opinions is highly contingent on social desirability concerns. Furthermore, attitudes may not be consciously accessible. Self-deception may drive people to negate or hide prejudice, or simply be not aware of their actual prejudice. In the 1980s and 1990s, a variety of alternative, mostly *implicit* measures, were developed in response to these new challenges. The most popular measure is the *Implicit Association Test*. This computerized instrument was originally proposed by Greenwald and his collaborators in 1998. Participants either press a key when two stereotypically linked words appear on a screen (e.g., a female name and a feminine profession), or press another key when there is no stereotypical association between the words. If reaction times are faster for stereotypical associations than for nonstereotypical ones, it is inferred that the individual is prejudiced. Other studies have measured unconscious nonverbal behaviors that express prejudice (e.g., de Lemus et al., 2012). Overall, however, clear demonstrations of the ecological validity of such measures are still awaited.

Consequences of Sexism

Sexism sustains social asymmetries in gender relations that typically advantage men. Sexist attitudes and opinions may produce discriminatory treatment such as unequal hiring and promotion practices, but also more extreme forms such as physical aggression and sexual violence. Past research has demonstrated a variety of detrimental discriminatory effects of sexism. The previous discussion of types of sexisms is important because each of the types maintains gender hierarchies in specific ways. In particular, it is important to distinguish between effects of hostile and benevolent sexism. One crucial difference is that HS is more easily challenged than BS. The sexist nature of benevolence is particularly difficult to identify as a corollary of discriminatory behavior (Barreto and Ellemers, 2013). Women are themselves vulnerable to, and thus accepting, this persuasive influence style. Conversely, they may more easily confront hostility. Explicit exertion of power and open acts of hostility are more likely to fuel a motive for collective action and protest (e.g., Becker and Wright, 2011). HS is therefore only effective if exercised infrequently, and/or when it is balanced with benevolence (Guinote and Vescio, 2010). Furthermore, recent research also suggests that confrontation of sexist behavior may have negative consequences on the evaluation of women, and that men judge as less attractive women who do not endorse traditional sexist beliefs (e.g., Barreto and Ellemers, 2013; Montañés et al., 2013). Thus, confrontation of sexism is not an easy option for women.

Another consequence of hostile sexism is the so-called *stereotype threat* effect. Women perform typically worse in stereotypically masculine tasks (e.g., a math test) as their gender membership is emphasized, even by means of subtle reminders (e.g., Spencer et al., 1999). However, similar damaging effects occur with benevolent sexism. A growing body of experimental evidence demonstrates that benevolence is harmful for women's feelings of competence and even actual performances (Dardenne et al., 2007; de Lemus et al., 2012; Guinote and Vescio, 2010). Women may underperform because of their fear of negative treatment if they reveal good performances. Agentic achievements by women are often judged as a violation of prescriptive gender stereotypes, and can thus lead to punishments, sabotage, and unfavorable evaluations, a phenomenon called *backlash* (Eagly and Karau, 2002; Rudman and Glick, 2008). Research on gender stereotypes has shown that the agentic descriptions of men match closely those of the normative white and healthy adults in general, whereas descriptions of women are embedded in group-specific, relational, and communal characteristics (see Wood and Eagly, 2010). Accordingly, the 'think manager–think male' phenomenon (Schein et al., 1996) shows that leaders in general are most often endowed with masculine, agentic characteristics. Female leaders must therefore face the conflicting demands of what it means to be a good leader and of what it means to be a woman (see Heilman et al., 2004). *Role congruity theory* (Eagly and Karau, 2002), as well as the *status incongruity hypothesis* (Rudman et al., 2012), examine antecedents and consequences of perceived violations of gender or status expectations. To avoid punishment, women tend to adapt their behaviors, for example, by negotiating lower salaries for themselves than for others, not promoting themselves in job-interviews, or hiding their performances (e.g., Rudman and Glick, 2008). These behaviors support the status quo of the gender hierarchy, and contribute to ban women from prestigious and high-status activities (Rudman et al., 2012). Thus, sexism does not only impact women's actual performances, but also leads to the downplaying, or the conscious hiding, of successful performances in traditionally masculine domains. Moreover, it has consequences on strategies for identity improvement. Indeed, if men pursue positive distinctiveness using agentic (i.e., status-relevant) dimensions, women, in a parallel process, pursue positive distinctiveness using communal (status-irrelevant) dimensions (e.g., Maccoby, 1998). From the social identity perspective, this difference can be conceived of as a *social creativity* strategy whereby members of a low-status group achieve positive distinctiveness despite their negative standing in the social structure (e.g., Tajfel, 1981).

Finally, at a macro-level, it has been found that national averages in HS and BS are positively related to gender inequality indexes in those nations (Rudman and Glick, 2008). Especially in traditionally male domains, men consider that the work domain is not suitable for women's qualities and competencies, whereas women accuse sexism targeted against them. More generally, the impact of communal stereotypes on women's professional careers is revealed by the consistent and substantive negative correlations between family life (as assessed, for instance, with family size) and professional life. The corresponding correlations typically reach outstanding positive levels among men (cf Lorenzi-Cioldi, 2002).

Conclusion

We conclude this article by emphasizing an important emerging sex difference in the expression of gender stereotypes and sexism. As we mentioned, until the 1970s men and women tended to acknowledge a social male advantage. Men were judged as more agentic (competent, independent, objective) and women as more communal (warm, expressive, interpersonal sensitive). Although sexism remains a complex societal phenomenon nowadays with both sexes expressing sexism against women, women's attitudes clearly evolved more rapidly than men's. Whereas men's attitudes have remained largely traditional, women's attitudes are moving toward more liberal views.

Sexual Behavior and Social Networks

Benjamin Cornwell and Rachel Behler, Cornell University, Ithaca, NY, USA

Abstract

Few things are more private than sexual behavior. Yet scholars increasingly see sexual behavior as being shaped by the broad social networks of kin, friends, and other contacts in which individuals are embedded. This article describes research that considers the relevance of these social (not sexual) contacts to a wide range of sexual behaviors, including sexual initiation, sex partner selection, expression of sexual identity, sexual frequency and problems, as well as risky behaviors such as unprotected sex, transactional sex, using drugs while having sex, and finding sexual partners online. We also address the finding that social networks are themselves shaped by these sexual behaviors. We close by discussing new directions for research on this topic.

Due to its implications for individual well-being, public health, fertility, and other important phenomena, research on sexual behavior has tremendous currency in the fields of sociology, demography, epidemiology, and medicine, among others. A rapidly growing literature shows that social networks play a major role in shaping numerous specific sexual behaviors. This work is distinct from but related to analyses of sexual networks themselves – webs of sexual connections among sex partners – by virtue of its focus on the importance of the nonsexual relationships that individuals maintain. As we will show, a variety of very private sexual behaviors – including such things as having unprotected sex and using drugs to enhance sex – are shaped by diverse social contacts including peers, friends, coworkers, neighbors, and family members. From early adolescence to later life, the influence of these types of social contacts is evident in individuals' desires for and attitudes toward sex, expression of sexual identity, exposure to sex partners and sex markets, and even the onset of sexual dysfunction.

The main goal of this article is to review evidence of strong relationships between aspects of individuals' social networks and their sexual behaviors. We begin by briefly discussing some of the mechanisms that are thought to give rise to this association, but we spend most of the article reviewing the evidence.

Why Do Social Networks Matter?

Social networks shape and channel individual behaviors through a variety of processes including social influence, role modeling, social support, and social control (e.g., see Friedkin and Johnsen, 2011). For one, sexual behavior is learned and diffused through close relationships. It is reinforced through network members' behavioral examples, the normative environments they create, and the pressures they exert, as well as individuals' perceptions of them, regardless of how accurate these perceptions are. Social network members can serve as sources of information about specific sexual behaviors (e.g., based on previous experience) as well as about potential sex partners, and they often introduce individuals to their future sex partners. Social network members often also exercise informal control over sexual behavior by creating restrictive normative contexts, by discouraging certain kinds of behaviors, and by exercising other forms of informal social control (e.g., ostracism). Finally, social network members are also responsive and react to each other's behaviors, thereby providing mechanisms by which sexual behaviors may reciprocally affect social networks.

The following sections address foundational and recent work which demonstrates associations between social networks and individuals' sexual behaviors. The remainder of this article is organized topically, addressing sometimes separate areas of research on different kinds of sexual behaviors.

Sexual Intention and Initiation

We begin by addressing sexual behaviors early in the life course. Most research shows that networks of peers shape individuals' sexual intentions and behaviors at an early age. A variety of mechanisms operate here, including adolescents' (perceptions of) network members' attitudes toward sex, their sexual behaviors, and their control efforts. Most studies agree that adolescents who perceive disapproval among their friends and/or parents with respect to adolescents having sex are more likely to remain abstinent or to delay sexual initiation (Buhi and Goodson, 2007). Adolescents' intentions and desires to have sex are also associated with the belief that most same-age peers have had sex (Miranda-Diaz and Corcoran, 2012).

Network members' narratives about romantic relationship trajectories and sexual milestones are also important. Harding (2007) suggests that adolescents from disadvantaged neighborhoods, for example, may have more lenient attitudes toward getting pregnant due to the larger number of competing sexual frames and scripts to which they are exposed. School-level norms are similarly influential in shaping adolescents' age of sexual initiation and risk of pregnancy (Teitler and Weiss, 2000). One study found that the efficacy of virginity pledges among adolescents is highly contingent on the number of other pledgers (Bearman and Bruckner, 2001).

Sexual Orientation and Identity

Social network members provide a normative environment that can be either permissive or intolerant with respect to a given sexual orientation (e.g., homosexuality), and thus may

 http://dx.doi.org/10.1016/B978-0-08-097086-8.35029-2

facilitate or obstruct certain sexual behaviors. Developmental perspectives on sexual orientation likewise argue that sexuality is partly a function of social pressures (e.g., toward conformity) and socialization, noting surprising levels of fluidity in the sexual orientations of young adults over time (see Saewyc, 2011). Other research shows that social network members' perceived emotional supportiveness is a key factor in determining whether sexual minorities disclose their sexual orientation (e.g., Latkin et al., 2012). Those who hide their orientation from close network members may be forced to engage in secretive (e.g., 'down-low') sexual behavior, which can lead to anonymous sex, transactional sex, and increased risk of HIV infection (e.g., Dodge et al., 2008), especially in the case of men who have sex with men (MSM) who also have sex with women.

Most research on the link between social networks and sexual orientation, however, focuses on the reverse process through which sexual orientation shapes social networks. A person's sexual orientation can affect how existing network members interact with them (see Julien et al., 1999). Sexual minorities perceive less support from family members than heterosexuals do, which leads sexual minorities to be more selective about their social network connections, sometimes leading to less kin-centered networks. In a similar vein, the joint social networks of both gay and lesbian partners tend to be larger and more comprised of friends than the joint networks of heterosexual couples.

Sexual Frequency, Satisfaction, and Problems

There is considerable evidence that having sex has numerous physical and mental health benefits (e.g., Brody, 2010). A large body of research on sexual health emphasizes the value of frequent sexual intercourse and satisfaction with sex, especially in committed relationships (e.g., Higgins, et al., 2011). Conversely, some researchers are interested in factors that contribute to sexual problems or dysfunction. Although much of this work focuses on health and medical factors, relationship quality, and other individual and dyadic factors, there is growing awareness of extradyadic social network influences on sexual functioning. We briefly discuss research on these topics in the following sections.

Sexual Frequency and Satisfaction

The extent of sexual activity in which individuals engage is related to their connectedness to nonsexual social contacts. Research shows that having supportive social ties increases the likelihood of engaging in and enjoying sexual activity (e.g., Prairie et al., 2011). They were also more likely to have reported being satisfied with their sexual activity. These associations may reflect benefits of psychosocial factors such as self-esteem, happiness, and life satisfaction for physical and sexual functions. As we will discuss below, maintaining extensive and wide-ranging social networks also increases the likelihood of being satisfied with one's sexual relationships, in part because it yields access to more diverse sex markets and thus increases the likelihood of finding a well-matched sex partner.

Sexual Dysfunction

Sexual problems and sexual dysfunction – for example, lack of interest in sex, difficulty achieving orgasm, erectile dysfunction (ED) – have also been conceptualized as social network issues. Existing research that emphasizes dyadic relationship qualities that diminish sexual arousal response (e.g., incompatible sexual scripts between partners or partner discord) already indirectly implicates sex markets and partner-matching processes (discussed below) in the genesis of sexual dysfunction (e.g., individuals who have smaller social networks find it more difficult to establish a sexually fulfilling relationship). Some research has linked men's risk of ED specifically to how men and their partners are connected through broader social networks. One aspect of social networks that is thought to increase heterosexual men's risk of psychological risk factors such as depression and anxiety is the extent to which men dominate their own social network resources. One study found that when a heterosexual man's female partner has more frequent contact with his network members than he does, he is 92% more likely to report having trouble getting/maintaining an erection and 78% more likely to have trouble achieving orgasm during sex (Cornwell and Laumann, 2011). The authors argue that this network arrangement introduces strain into men's sexual relationships by decreasing partner satisfaction and sense of privacy and autonomy. Little is known about what role social networks play in the genesis of sexual problems in women.

Extramarital Sex

The influence of social networks extends to the practice of extramarital sex. In general, extramarital sex is more likely among men, and most of the work that has been done on the social network determinants of extramarital sex focuses on men. Research on this population documents strong peer influences on extramarital sex. Men whose friends and other confidants engage in extramarital sex (with sex workers or otherwise) are also more likely to engage in extramarital sex (Vanlandingham et al., 1998). Another important aspect of social networks in this respect is the extent of overlap between sex partners' social networks. Network overlap increases social support, sense of couplehood, and the capacity for mutual monitoring. Among both men and women, spouses who share numerous mutual social network members are less likely to have extramarital sex (Treas and Giesen, 2000).

Sex Partner Selection and Sex Markets

Social networks directly shape processes of sex partner selection and matching. Network contacts provide information and advice about potential sex partners, and can make introductions between them. They can also exert pressure to date certain types of people or to pursue certain types of relationships (Laumann et al., 2004). Research suggests that roughly 60% of all partnerships (including marriage, cohabitation, and short-term relationships) result from an introduction by a mutual acquaintance. Mutual friends are responsible for 30% of those introductions, while family members, coworkers, and

classmates together account for the remaining 30% (see Laumann et al., 1994). The most common way people find their partners is through introductions made by their friends. It is worth noting that how these introductions are made is related to the level of commitment within sexual relationships.

Sex Markets and Affiliation Networks

The concept of sex markets reframes the search for sex partners, identifying the intersection of social networks and physical spaces as markets in which participants shop for sex partners interested in specific sexual activities (e.g., casual sex). Sex markets arise from the combination of informal networks of individuals who facilitate introductions to sex partners and organizations and other places that constitute opportunity structures for meeting sex partners. Examples include places that host singles' nights, café speed-dating events, and dance clubs. The 'affiliation networks' of places that form sex markets (see Frost, 2007) shape and are shaped by the sexual behavior of their constituent members. Sex markets are socially constructed by their members – defined by the expectations of their participants and by their embeddedness in particular local social and cultural milieus. Participants hold expectations about the types of sexual relationships (e.g., short-term versus long-term), the sexual scripts, and the 'rules of exchange' that operate within a given market. Accordingly, different places cater to different sex markets. The speed at which sexual activity occurs and which sexual acts take place in the relationship is linked to the place partners were introduced. For example, partners who meet in a bar are more likely to report having sex within the first month of the relationship than those who meet in school (Laumann et al., 1994). Larger spaces, like neighborhoods, are often composed of multiple overlapping sex markets, including adjacent bars that cater to heterosexual or homosexual clientele or public parks that attract people who are looking for anonymous short-term sex (Laumann et al., 2004). Thus, researchers have begun to examine individuals' positions within the networks of places that form sex markets to understand individuals' risk of contracting or spreading sexually transmitted diseases (STDs) such as HIV/AIDS (e.g., Frost, 2007).

Online Social Networks

Online social networks are increasingly used as sex markets. This is especially true of populations in 'thin markets,' or places in which few potential partners exist who meet baseline criteria for matching, such as LGBT people searching for other LGBT partners. Online networks expand an individual's effective search area beyond both the geographic boundaries formed by their neighborhoods and the social boundaries formed by their personal social networks. Men and women in the 35- to 50-year-old age range are the most likely to meet online (Rosenfeld and Thomas, 2012). As of 2009, the Internet was the third-most-common way heterosexuals found their partners, following introductions by friends and meeting in bars. Online meetings accounted for 22% of heterosexual partner meetings and 60% of same-sex partner introductions. This new role of the Internet as a relationship broker has also been accompanied by declines in the role of personal social networks and local places in forging sex partnerships (Rosenfeld and Thomas, 2012). As we will discuss in greater detail below, this is a disturbing trend in light of the fact that people who use online social networks are also more likely to report engaging in a number of risky sexual behaviors, including having unprotected sex, having sex with multiple partners, using drugs during sex, and having sex with a known HIV-positive partner (e.g., see Benotsch et al., 2002; Horvath et al., 2008).

Risky Sexual Behavior

Some research on the role played by social networks in sexual behavior is motivated by public health concerns, especially regarding the spread of STDs like hepatitis and HIV. Much research has focused on how sexual and drug-sharing networks, or 'risk networks,' affect disease diffusion, giving rise to the field of network epidemiology. But researchers are also increasingly interested in the role of other social network contacts who may not be risk network partners (e.g., family members and close friends) in encouraging, facilitating, discouraging, or obstructing sexual behaviors that can increase STI (sexually transmitted infection) transmission (e.g., Tyler, 2008). This includes a range of potentially risky sexual behaviors, including engaging in unprotected sex, sex with multiple partners, engaging in sex while under the influence of drugs or alcohol, and transactional sex.

Unprotected Sex

One of the most-studied questions in this area of research is how social network members shape individuals' beliefs about and use of condoms during sex. Some research highlights the importance of parents. Wolff and Crockett (2011) find that adolescents who receive more support from their parents are less likely to have unprotected sex. Likewise, those who communicate with their parents about sexual behavior are less likely to have unprotected sex (Hadley et al., 2009). Other network members – especially friends – may influence individuals' tendencies to use condoms by serving as role models, by exchanging information, and/or by shaping the normative environment. Choi and Gregorich (2009) find that women are more likely to report partner condom use when they have at least one confidant who encourages condom use. Condom use is also greater among those whose confidants know each other, suggesting either that perceived agreement among confidants or confidants' abilities to exercise informal control affects women's safe sex practices. Other work shows that adolescents whose friends engage in deviant behavior (e.g., smoking and drinking) are more likely to engage in unprotected sex (Wolff and Crockett, 2011), suggesting that more permissive normative environments in general increase the risk of unprotected sex.

Even among at-risk populations, such as sex workers, network influence remains strong. Latkin et al. (2003) found that, among impoverished men and women who are at high HIV risk, having friends who talk about condoms, encourage condom use, and using condoms increases the likelihood of condom use. Condom use is more likely among male clients

of female sex workers when they perceive that at least some of their male social network members also used condoms consistently (e.g., Barrington et al., 2009). Other work shows that MSM are more likely to engage in unprotected anal intercourse when they perceive that their nonsex partner confidants likewise engage in such behavior (Schneider et al., 2013). Structural features of individuals' social networks may also matter. Those who have dense networks are more likely to perceive high levels of condom use among their network members than those whose networks are more sparse (Barrington et al., 2009).

Use of Drugs during Sex

A growing concern among health researchers is the practice of using drugs – such as inhaled amyl nitrate (poppers) and amphetamines – to enhance sexual experience. The use of drugs during sex is associated with risker sexual behavior (e.g., rough sex, unprotected sex) and thus heightened risk of HIV transmission, in part because drugs effectively reduce inhibition and rational decision-making (see Stall and Purcell, 2000). The use of drugs during sex may be greater among individuals who are already at greater risk of STD infection, especially homeless youth and MSM (Stall and Purcell, 2000). Various classes of drugs have become widely established as 'drugs of choice' for engaging in high-risk sex in a number of contexts, especially stimulants, poppers, and ED drugs (e.g., Mansergh et al., 2006). One recent concern is over the use of multiple drug use during sex, as this further increases the risk of unsafe sex practice and HIV infection (Ostrow et al., 2009). Recent research has discovered a strong link between the use of drugs during sex among nonsex partner social network members and individuals' own use of sex drugs. This has to do with individuals' perception of approval of such behavior among their network members, in that the presence of even one enabling social network member in one's confidant network is associated with significantly increased risk of sex-drug use, even after controlling for those network members' perceived use of sex drugs (Schneider et al., 2013).

Multiple Sex Partners

Having sex with numerous people over a short period of time or with multiple partners (simultaneously or in separate but concurrent relationships) is a major risk factor for STI transmission. The research that exists on how social networks shape the likelihood of having multiple sex partners focuses on both social influence processes and sex markets. On the one hand, research on homeless youth suggests that those who have a close social network member (e.g., friend) are less likely to have multiple sex partners (Ennett et al., 1999). On the other hand, a study of impoverished urban African-American women found that the likelihood of having multiple sex partners increases with personal social network size, possibly indicating greater access to potential partners through network channels (Neblett et al., 2011). Finally, the likelihood of having sex with multiple partners is positively associated with the extent of alcohol and drug use among social network members (e.g., Neblett et al., 2011), suggesting that the broader normative environment is important.

Transactional Sex

Exchange-oriented, or 'transactional,' sex refers to the dynamic wherein sex is offered by a participant in return for something else, frequently drugs or money. Transactional sex is often conceptualized in terms of prostitution, but it can also be used to describe less-commercialized forms of sex, such as courting rituals that dictate a 'tit-for-tat' pattern in which gifts are exchanged in return for sexual favors. Transactional sex is frequently associated with risky behavior because of the power dynamic that can prevent the party offering sex from utilizing protection. This is especially true in the context of 'survival sex,' which involves transactional sex as a means acquiring money, food, or even shelter. Social network members may affect transactional sex behavior both through conventional social influence pathways or through sheer abandonment. Survival sex is especially likely among disadvantaged youths who have been alienated by close social network members (especially family), often because of their sexual orientation (Ennett et al., 1999). Research also shows that one's likelihood of engaging in transactional sex is a function of the social network environment. One study reports that women who believed that their core social network members (especially friends) exchanged sex were more than twice as likely to exchange sex as women who did not believe that their friends exchanged sex. At the same time, perceived approval of transactional sex among these women's peers cut their likelihood of exchanging sex by more than half (Davey-Rothwell and Latkin, 2008). It is important to note that gender is a salient dimension of such exchange-oriented sex, as men are much more likely to purchase sex and women are more likely to sell it (Latkin et al., 2003).

Conclusion

This article has highlighted the relevance of broad networks of (nonsexual) social contacts – including kin, friends, peers, and others – to seemingly private sexual behaviors. Social network members create the normative contexts in which sexual behaviors and intentions emerge, they serve as role models, and they can facilitate or impede sexual partnering. Social networks can therefore both facilitate and suppress sexual behaviors ranging from adolescent sexual initiation to survival sex.

There are several key challenges facing researchers in this area. To understand the implications of nonsexual social networks for consequential sexual behaviors and problems, this work needs to be more closely merged with network-epidemiological research on *sexual* networks. An important but largely unaddressed question is to what extent individuals' social and sexual networks overlap. Some social contacts (e.g., friends) may also be sex partners or more distant members of one's sexual network. Overlap between sexual and social networks can occur when people are alienated from their social networks (e.g., families) and/or when social contacts (e.g., friends) become sex partners (and vice versa). As such, estimates of social network influence may actually partly capture sex partner influences. The assessment of the selective emergence and extent of such network overlap is an important direction for research. Related to this, the vast majority of the above research is cross-sectional and is plagued by

endogeneity. Social network researchers are actively working on methods to distinguish between the effects of social networks on behavior and the reciprocal effects of that behavior on the structure and composition of networks. An important step in this direction is the collection of longitudinal data that captures changes in individuals' social and sexual networks.

Finally, the promise of this area of research lies in the prospect that it can be used to attenuate important social problems, such as the spread of HIV/AIDS as well as some of the risky behaviors that contribute to it, such as the use of drugs during sex and survival sex. Fortunately, social networks are figuring increasingly prominently in intervention studies that focus on such behaviors. Recent interventions have explored the prospect of using the power of social network members' influence to increase condom use and other HIV-prevention efforts among adolescents, sex workers, and other at-risk populations (see Barrington et al., 2009; Wang et al., 2011), to reduce transactional sex among women (Davey-Rothwell and Latkin, 2008), and numerous other applications. Greater collaboration between social network researchers and public health researchers is needed to ensure that these interventions harness the full range of mechanisms through which various social network features may affect relevant sexual behaviors.

Sexual Debut

Anthony Paik, University of Iowa, Iowa City, IA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article presents an overview of sexual debut, which refers to an individual's first experience with vaginal intercourse. Sexual debut represents not only an important life course transition, but also a demographic behavior with significant implications for sexual and reproductive health. This article summarizes cross-national variation and historical trends in sexual debut in both developing and developed countries. It also describes determinants, concomitant behaviors, and consequences of sexual debut.

Sexual debut, or sexual initiation, refers to the first penile–vaginal intercourse during an individual's lifetime. The onset of sexual intercourse is particularly significant because of its implications for gender, the life course, sexual and reproductive health, the formation of cohabiting and marital unions, and human-capital accumulation. There is substantial historical and societal variation in sexual debut as it pertains to its timing, whether this transition occurs with or before marriage, and the degree to which there are gender differences. This article summarizes the following: recent patterns and trends across developed and developing countries since 2000; systematic reviews of risk and protective factors influencing its timing among youth; the partnership contexts and practices under which this transition occurs; and its implications for sexual and reproductive health outcomes, such as the acquisition of sexually transmitted infections, fertility, union formation, and human-capital accumulation.

The onset of sexual intercourse can be understood using one of several conceptual frameworks. First, sexual debut is linked to the transition to adulthood. A life course perspective highlights the social construction of cultural categories linked to physiological aging. From this perspective, sexual debut may be understood as a normative behavior linked to particular life stages (e.g., adolescence or adulthood), the transition from adolescence to adulthood, and physiological processes of aging, including pubertal development (Udry and Campbell, 1994). Second, social-control perspectives emphasize how the onset of sexual intercourse is a behavior governed by major societal institutions, such as the law, religion, and the family (DeLamater, 1981). Sexual debut occurs within the context of legal and moral prescriptions as well as the degree to which societies are permissive of premarital sexual intercourse. Finally, a third major framework for studying sexual debut is through the lens of gender (Schwartz and Rutter, 1998). The onset of sexual intercourse can be viewed as a gendered process or as a way of doing gender. Taken together, these frameworks highlight the importance of aging, gender, and social institutions for defining the normative and nonnormative contexts for the onset of first sexual intercourse.

Cross-National Variation and Trends

Cross-national comparisons indicate that there is substantial variation in the timing and context of sexual debut. **Figure 1** presents proportions of male and female 15–19 years olds who experienced first sexual intercourse based on representative surveys gathered since 2005 across 21 developing countries, Canada, and the United States. It is worth noting that this figure has relatively few data points from Europe, Asia, and South America. There is a large cluster of countries – Kenya, Uganda, Tanzania, Canada, United States, Zambia, Dominican Republic, Malawi, and the Democratic Republic of Congo – where a third to half of male and female 15–19 years olds experienced the onset of first intercourse. In contrast, China is the one country where the vast majority of 15–19 years olds, more than 90%, have not experienced sexual debut. Large proportions of 15–19 years olds did not report the onset of first sexual intercourse in Albania and Rwanda as well.

Figure 1 also shows substantial gender differences in sexual debut among 15–19 years olds in some countries. In Ethiopia, India, Nepal, Senegal, Zimbabwe, Ghana, and Nigeria, 1.5–3 times as many girls and women experienced sexual debut, compared to boys and men of the same age. For example, in India, 28% of female 15–19 years olds have had sexual intercourse, compared to 11% of male youth. This disparity suggests that many sexually active female youth become involved with older men in these countries. In contrast, the proportion of sexually experienced male youth, compared to female youth, is nearly four times as large in Guatemala and twice as large in Moldova.

To understand trends, Figure **2**(a) and 2(b) presents estimates of sexual debut before age 15 among female and male youth by cohorts from the 1990s and 2000s in selected African countries. Prior research found that the proportion of female youth experiencing sexual debut before age 15 decreased when comparing cohorts from the 1970s against the 1990s, but showed an increased proportion of male youth (Wellings et al., 2006). **Figure 2(a)** indicates that in 11 out of 12 African countries, the proportion of female youth who experienced sexual debut by age 15 had declined in the 2000s, compared to the 1990s. Moreover, with the exception of Mozambique, less than one-sixth of female youth became sexually active by age 15 across all of these countries. In contrast, based on **Figure 2(b)**, trends in sexual debut for male youth are less consistent. Most countries have declines in the proportion of male youth who experienced sexual debut by age 15 when comparing cohorts from the 1990s against the 2000s, but Malawi, Mozambique, Rwanda, and Uganda had increasing percentages over time. Still, in 8 out of 11 countries less than

Figure 1 Proportion of 15–19 years olds that ever had intercourse by country and gender (national surveys since 2000). Sources: Anderson, R., Panchaud, C., Singh, S., Watson, K., 2013. Demystifying Data: A Guide to Using Evidence to Improve Young People's Sexual Health and Rights. Alan Guttmacher Institute, New York; Copen, C.E., Chandra, A., Martinez, G., 2012. Prevalence and Timing of Oral Sex with Opposite-Sex Partners among Females and Males Aged 15–24 Years: United States, 2007–2010. National Health Statistics Reports; No 56. a sixth experienced sexual debut by age 15 in the 2000s. The long-run trend for female youth in many African countries is an increasing age of first sexual intercourse, whereas for male youth the trend is more mixed.

Longer trend data are available for developed countries. The median age of first intercourse has been declining since the 1950s in a number of developed countries, including Greece, Portugal, Iceland, Denmark, Finland, Norway, France, Switzerland, Great Britain, Belgium, the Netherlands, France, and the United States (Bajos et al., 2010; Finer, 2007; Teitler, 2002). This pattern is larger for female youth due to the fact that male youth tended to become sexually active earlier across all of these countries. However, at least in the United States, data since 2000 indicate that the proportion of sexually active youth is no longer increasing (Santelli and Melnikas, 2010).

A key issue is whether sexual debut is premarital or occurs within the context of a cohabiting or marital union. Many developed countries show a pattern of relatively early sexual debut but delayed union formation. Figure 3 presents median ages of first sexual intercourse and first union formation (cohabitation or marriage) among women aged 20–24, based on demographic health surveys since 2003, which showed considerable variation. For most countries, the median age of first sexual intercourse is lower than the median age of first union, but in three countries – Ethiopia, India, and Nepal – the latter is the same as or lower than the former. This suggests that first intercourse occurs within the context of marriage for many female youth in these countries and that many become married during adolescence. In other countries, such as Mozambique, Uganda, and Tanzania, the median age of first sex is lower than the median age of first marriage, yet both still occur relatively early. In Columbia and Peru, the median age of first sex is more than 3 years lower than the median age of marriage, whereas both occur relatively late in Rwanda, Philippines, and Albania.

Correlates and Contexts of Sexual Debut

This section focuses on nonmarital sexual debut, which is age graded. In an analysis of a recent cohort in the United States, for example, the proportion of female youth who had experienced sexual debut jumped from around 10% at age 14 to nearly 70% by age 18 (Finer, 2007). The substantial age grading of sexual debut reflects its formal regulation via age of consent laws as well as beliefs and attitudes about the appropriateness of becoming sexually active.

Determinants of Sexual Debut

Table 1 lists correlates of the occurrence or timing of adolescent sexual debut based on three recent systematic reviews of the literature in developing countries (Mmari and Blum, 2009), the United States (Buhi and Goodson, 2007), and the United Kingdom (Hawes et al., 2010). In terms of personal factors, older age of menarche and spermarche are associated with delayed sexual debut. For female youth, in particular, age of menarche is one of the major determinants of later age of sexual debut. An explanation for this association is that early pubertal development may cause individuals to treat younger girls as if they were older. Other personal factors include self-esteem, intentions to have sex, and alcohol or drug use. Not surprisingly, intentions to have sex are associated with increased likelihoods to experience early sexual debut, whereas

Figure 2 (a) Percent of female youth who had first intercourse by age 15. (b) Percent of male youth who had first intercourse by age 15. Note: National estimates are based on respondents who were 15–24 years old for the 2000s and 20–24 for the 1990s. Sources: Anderson, R., Panchaud, C., Singh, S., Watson, K., 2013. Demystifying Data: A Guide to Using Evidence to Improve Young People's Sexual Health and Rights. Alan Guttmacher Institute, New York; Bankole, A., Singh, S., Woog, V., Wulf, D., 2004. Risk and Protection: Youth and HIV/AIDs in Sub-Saharan Africa. Alan Guttmacher Institute, New York.

self-esteem is associated with delay. Alcohol and drug use are associated with an increased likelihood of early sexual debut. Substance use may not only impair youths' decision making, but also expose them to environments and individuals where sexual activity is more likely to be normative.

A number of family characteristics have been linked to the timing of sexual debut, including parents' background characteristics, family structure, and aspects of parent–child relationships. Higher socioeconomic status (SES) and being raised by two parents is associated with older age of first intercourse, whereas residential mobility and having a mother or sibling who had children early are linked with early sexual debut. Children in higher SES households may tend to have higher opportunity costs of becoming sexually active. Consistent with social control perspectives, parental closeness, parental monitoring, and parental disapproval of sex have all been linked to later age of sexual debut.

School and community-level factors associated with the delay of sexual debut include school enrollment, educational aspirations, academic performance, attending a high-quality school, receiving sex education, and the frequency of religious service attendance. The effect of schooling on the timing of sexual debut is notable; it suggests that educational attainment increases the opportunity costs of becoming sexually active. Schooling is also associated with later formation of a first sexual union. From a policy perspective, this suggests that enhancing educational opportunities in many nations, particularly for female youth, will lead to delayed sexual debut. Another notable association is the impact of sex education on sexual debut in the United Kingdom. Sex education represents an important intervention that could be administered across numerous contexts. It is important to note that the efficacy of abstinence-only sex education is questionable; quasi-experimental studies suggest that it is not effective in comparison to abstinence-plus or comprehensive sex education (Trenholm et al., 2008).

Finally, peer approval of sex and peer sexual behavior are associated with early sexual debut. It is important to note

Figure 3 Median age of first intercourse and first sexual union among women (20–24 years old). Source: Anderson, R., Panchaud, C., Singh, S., Watson, K., 2013. Demystifying Data: A Guide to Using Evidence to Improve Young People's Sexual Health and Rights. Alan Guttmacher Institute, New York.

that research in this area has relied on respondents' perceptions of their peers' sexual attitudes and behaviors. As such, correlations between these factors and the timing of sexual debut may reflect projection bias – that is, the tendency of survey respondents to ascribe their attitudes and behaviors on their peers. Research is needed that utilizes peer measures that are not based on survey respondents' perceptions.

Table 1 Correlates of early sexual debut

Variables	*Developing*	*US*	*UK*
Personal			
Age of puberty			–
Intentions to have sex		+	+
Self-esteem		–	
Alcohol or drug use	+		+
Family and social background			
Mother had children at young age			+
Parents' SES			–
Family instability	+		+
Older sibling pregnant as an adolescent	+		
Residential mobility	+		
Parental closeness and relationship quality		–	
Parental control, monitoring, and supervision		–	–
Parental disapproval of sex		–	
Schooling and community level			
School enrollment	–		–
GPA	–		
Educational aspirations	–		
School quality			–
Sex education			–
Religiosity			–
Peer and partner-level			
Perceive friends have sex	+	+	
Peer approval of sex		+	+

+ denotes an increasing risk of earlier sexual debut; – indicates a correlate that delays sexual debut.

Concomitant Aspects of Sexual Debut

In addition to the timing and determinants of sexual debut, there are a number of concomitant aspects. Researchers have focused on the relationship contexts of sexual debut as well as partner characteristics, contraceptive use, alcohol or drug use, degree of wantedness and consensuality, and associated emotions and feelings. In general, younger ages of sexual debut have been linked to unprotected sex, impaired judgment due to alcohol use, and unwanted experiences (Hawes et al., 2010; Paik, 2011). Research also focuses on the relationship contexts of sexual debut, such as whether partners are dating or casual, age differences between partners, and concomitant sex practices. A systematic review of 268 qualitative studies of sexual behavior among youth identified a number of themes related to sexual debut (Marston and King, 2006). Specifically, possession of condoms, which implied to many youth sexual experience and the lack of trust, were particularly stigmatizing for female youth. These beliefs may impede the utilization of condoms at first sexual intercourse. Likewise, displaying chastity was a particularly important theme for female youth.

Consequences of Sexual Debut

The timing and concomitant aspects of sexual debut have been linked to sexual and reproductive health, including sexually transmitted infections, fertility outcomes, and union formation. For example, a systematic review of the literature showed that early sexual debut was associated with an increased risk of HIV among sub-Saharan African women (Stöckl et al., 2012). This increased risk is linked to a number of factors, including subsequent risky sexual behavior (e.g., increased numbers of sex partners), partner characteristics, and possibly biological factors. Also, early sexual debut is associated with a number of fertility outcomes, such as early pregnancies, abortions, and live births (Santelli and Melnikas, 2010), because of the longer exposure period, decreased likelihood of using contraceptives, and increased likelihood of having more partners. Finally, research has linked early sexual debut to early union formation (Miller and Heaton, 1991), lower educational attainment (Sabia and Rees, 2009), and divorce (Paik, 2011).

Current and Emerging Directions in Theory and Research

Methodological Issues or Problems

Sexual debut is correlated with numerous outcomes. Some of these are direct consequences of early sexual debut, whereas the casual linkages can be indirect as well, resulting from increased exposure to sexual activity. In these cases, the causal linkages are fairly clear. Support for causal arguments are less clear for other associations, such as those between sexual debut and subsequent social and demographic behaviors, such as educational attainment, union formation, and divorce. Here, these associations may not be causal, so there is a need for research that can make more credible causal claims linking the timing of sexual debut to subsequent demographic and social behaviors. Also, research on the timing of sexual debut relies on self-reports. However, experimental research suggests that men may overstate their sexual activity, whereas women will underreport it. Few studies have sought to examine the extent of these biases regarding sexual debut.

Future Research

There are a number of current and emerging research issues regarding the timing of sexual debut. First, there is burgeoning interest in the relationship contexts of sexual behavior. For many, sex occurs with the context of sexual unions, such as marriage and cohabiting relationships. Among noncohabiting relationships, sex is often embedded in romantic or serious relationships. Recently, there is increased attention to non-romantic contexts of sex, such as casual sex, but relatively little attention has focused on this issue with respect to sexual debut. A second theme of current interest is the extent to which sexual debut is completely voluntary and wanted. For example, in the United States, a substantial percentage of individuals reported that the onset of first intercourse was not completely wanted (Paik, 2011). There is a strong age grading to this, yet there is a need for more research. Finally, an emerging theme is the need for increased attention to contextual and cultural factors associated with the timing of sexual debut. Research has focused primarily on individual level and social background predictors of the timing of first sex. At the same time, there is substantial cross-national variation, which highlights the importance of varying social contexts and cultural beliefs that give rise to this variation. In sum, sexual debut is not only a significant life course transition, but one that has important policy implications.

Abstract

Over the past two decades, sexual dysfunction in men and women has been the topic of significant inquiry and research. Included in this article are explanations of each of the dysfunctions and their relationship to the sexual response cycle, discussion of the classification systems, and estimated prevalence rates for both men and women. In addition, the authors discuss common risk factors and mention typical treatment strategies currently available for each of the dysfunctions.

General Orientation

This article focuses on the sexual dysfunctions, that is, problems in responding adequately to achieve a sexually satisfying life, usually within the context of a sexual relationship. Problems typically categorized under the sexual dysfunctions include, for example, a man's inability to get or keep an erection or a woman's inability to reach orgasm – problems specific to adult sexual behaviors that interfere with having a sexually fulfilling relationship. Each type of disorder has its own etiology, causes, and effects, and each is typically treated by a specialist having a deep understanding of the issue as well as effective treatment strategies. Professionals who deal with any of the above disorders typically use diagnostic guides such as the *Diagnostic and Statistical Manual of Mental Disorders* (DSM; American Psychiatric Association, 2000; 2013) or the *International Statistical Classification of Diseases and Related Health Problems* (ICD; World Health Organization, 2013) to identify, classify, and diagnose the problem. New editions have provided revision to the classification systems, as increased understanding and further research of the disorders is constantly developing. This article provides information primarily based on the *Diagnostic and Statistical Manual of Mental Disorders, 4th Edition, Text Revision* (DSM-IV-TR) and ICD-10 classification systems, while noting changes made in the recently released DSM-5 classification system. The ICD-10 classification is closely aligned with the DSM-IV-TR, and the ICD-11, with its anticipated 2015 release, is expected to be organized in a manner similar to the DSM-5.

Understanding Sexual Response

Sexual response is complex, requiring specific preconditions, incorporating a variety of behavioral responses, and including an array of psychosocial and interpersonal factors that relate to emotional, cognitive, and relationship dimensions. However, for purposes of simplification, it is usually divided into three phases: desire, arousal, and orgasm (Masters and Johnson, 1966; Kaplan, 1974). More recent refinement distinguishes 'unprompted' or 'spontaneous' desire from arousability, the latter referring to sexual desire derived from a specific individual, object, or context. Further conceptualization has included separate pain–pleasure dimensions (Schover et al., 1982) as well as attention to other factors such as the feelings, motivations, and attitudes that surround the sexual act (Byrne and Schulte, 1990).

The classification of sexual dysfunctions has evolved, to a large extent, from the conceptual models mentioned above and includes

- a lack of desire, also known as hypoactive sexual desire disorder (HSDD),
- problems with either physiological (e.g., genital) or psychological sexual arousal,
- disorders of ejaculation/orgasm, most typically premature ejaculation (PE) in men and inhibited orgasm in men and women, and
- problems with painful intercourse and/or sexual aversion, both of which may lead to avoidance of sexual intimacy.

Sexual problems are also characterized as either situation-specific (including person) or generalized, and as either lifelong or acquired (through either pathophysiological developments or sexual experiences). As mentioned above, several classification systems are currently in use to define sexual dysfunctions; DSM-IV-TR (American Psychiatric Association, 2000), the relatively new DSM-5 (American Psychiatric Association, 2013), ICD-10 (ICD; World Health Organization, 2013), and International Society of Sexual Medicine (McMahon et al., 2008) are among the more common ones. Each system has categories related to a lack of sexual interest/desire, the inability to become adequately aroused either physically (in terms of genital response) or psychologically (feeling aroused), and problems with orgasm – either reaching orgasm too quickly or reaching it only after a very long time, or perhaps not at all (see **Table 1**). Together, desire, arousal, and orgasm are sometimes referred to as the 'sexual response cycle', and the approach that considers potential biological, psychological, and relationship factors that affect the sexual response cycle is referred to as the 'biopsychosocial' model of human sexual response. An overall summary of risk factors for sexual problems and treatment approaches to those problems, as modeled by the biopsychosocial approach, is provided in **Figure 1**.

While the various components of the sexual response cycle are essentially the same across the sexes, they may be manifested differently as the result of different genital structures. For example, physiological genital arousal is manifested by penile erection in men; the analogous response in women is vaginal lubrication and clitoral erection. In addition, as is apparent

Table 1 Classification of sexual dysfunctions and defining features

	Name	*Defining features*
Disorders of desire/interest and arousal	Male hypoactive sexual desire disorder (HSDD)	Diminished or absent desire for sexual activity
	Male erectile disorder/erectile dysfunction	Difficulty getting and keeping an erection
	Female sexual interest/arousal disorder	Diminished or absent interest in sexual activity, diminished or absent subjective arousal and excitement during sexual activity, difficulty attaining and maintaining adequate genital arousal (e.g., lubrication or vaginal swelling)
	Sexual aversion disorder (SAD) (male and female)	Persistent or frequent strong aversion to or avoidance of sexual activity with a partner *This disorder removed from the DSM-5
Disorders of orgasm/ejaculation	Male orgasmic disorder/inhibited ejaculation (IE)	A delayed or complete inability to reach ejaculation following a normal sexual excitement phase
	Premature ejaculation (PE)	Ejaculating very quickly because the man is unable to delay it
	Female orgasmic disorder (FOD)	Delayed or inhibited orgasm following a normal sexual excitement phase
Disorders of pain	Genitopelvic pain/penetration disorder (male and female)	Recurrent or persistent genital pain that interferes with sexual activity (categorized in DSM-IV-TR as male dyspareunia, female dyspareunia, and female vaginismus)

later in this article, sexual dysfunctions related to each component of the sexual response cycle are distributed differently across men and women, with men having greater problems with erection and ejaculating too quickly, and women having greater problems with sexual desire and reaching orgasm.

The above segmenting of the sexual response cycle into specific phases is helpful to health professionals because problems with each phase have their own etiology and causes and therefore may require their own specific treatment. Nevertheless, these categorizations have little meaning for most lay people who view their sexual experiences as holistic events that are either 'satisfying or not satisfying'. Therefore, when dealing with sexual dysfunctions, the health professional may need to spend significant time helping the client and his or her partner understand not only these elements of sexual response, but also each of their potential causes. Furthermore, although an individual or couple may be dissatisfied with their sexual response and relationship, this does not necessarily signal a dysfunction – specific criteria are used for diagnosing a sexual dysfunction, and unless an individual meets those criteria, he or she may have a sexual problem or be 'sexually dissatisfied', but not 'sexually dysfunctional'. Finally, healthy sexual relationships are not characterized merely by the absence of dysfunctional response. Key elements of healthy sexual relationships include passion, intimacy and caring, and commitment (Sternberg and Barnes, 1988). Passion typically involves such characteristics as sexual feelings, physical attraction, and romantic love. Intimacy deals with dimensions of affection, caring, and expressiveness and the willingness to communicate and share beliefs, attitudes, and feelings. Commitment refers to the decision to be with one partner and to work hard to maintain the relationship. As many sexual problems are rooted in couple's disparate expectations and emotional struggles, including the different ways in which these elements are often played out by each of the sexes, most sexual problems benefit from attention to general relationship factors as well as to specific sexual response issues.

Epidemiology, Terminology, and Related Issues

Epidemiology is a branch of medicine that deals with the frequency, distribution, and spread of disease or health-related events within populations, with attention to those factors that cause, influence, and control them. With respect to sexual dysfunction, epidemiologists are more likely to refer to 'risk' factors than 'causal' factors. That is, certain predisposing biological, psychological, and relationship factors may place a man or woman at higher probability for a particular sexual dysfunction, but these factors do not, in the classic sense of the word, determine or cause the dysfunction. Specifically, men or women having similar sets of risk factors may exhibit very different levels of sexual functionality (or dysfunctionality).

Epidemiologists also distinguish between incidence and prevalence. Incidence is the number of new cases within a population over a given period of time. Prevalence, on the other hand, is the total number of cases within a population at a given time. With respect to sexual dysfunction, prevalence, not incidence, is more typically reported. As indicated previously, the prevalence rate for each defined sexual dysfunction is different, and the prevalence rates differ across the sexes as well.

Determining the prevalence of any sexual dysfunction in men and women is challenging in that the reported occurrence of any sexual problem is subject to numerous factors. Specifically, defining a problem as a sexual dysfunction requires that the functional impairment meet specific criteria – in many instances, a person may view his or her response as problematic, but it may not meet the criteria necessary for a clinical diagnosis. Even more problematic, often the operational criteria for diagnosing a dysfunction differ from one classification system to the next – the use of different criteria will affect

Figure 1 A model illustrating common risk factors for sexual dysfunctions in men and women, including how, based on a biopsychosocial model, psychosocial factors and biomedical interventions may affect the problem and its outcome.

which persons are included in the dysfunctional classification and which are excluded.

Furthermore, for persons to be classified as dysfunctional requires that they recognize the symptoms and potentially define themselves in this category. And, issues of privacy, discretion, and sometimes stigmatization may inhibit people from disclosing what might be viewed as 'inadequacies'. Additionally, a diagnosis of a dysfunction generally requires that the individuals find the symptoms distressing, although not all specialists agree on the need for inclusion of this criterion.

Finally, prevalence is a moving target. For example, for some people, the problem may be transient, as when life stressors or particular sensitivity or vulnerability to specific relationship interactions contribute to or intensify a problem that is initially 'subclinical' – issues that DSM-5 has attempted to address in part by requiring that symptoms be present for a minimum duration of 6 months and by including more precise severity criteria. Changing cultural attitudes, expectations, and acceptance regarding men's and women's sexual problems may influence the willingness to acknowledge and report sexual problems – as such, tendencies for self-reporting problems will change as well. Such factors, along with general health and diet, result in prevalence rates that differ across time and across geographic regions of the world. And, finally, for those sexual dysfunctions that are partly age related (e.g., problems with erection and/or sometimes sexual interest), as the age demographic changes, so also does the prevalence (Rowland, 2012).

Epidemiology of Men's Sexual Dysfunctions

In this section, prevalence rates and risk factors for disorders of desire, arousal (including erectile problems), and ejaculation in men are reviewed, with comment on the prognosis and

treatability of each of the dysfunctions. Pain disorders and sexual aversion are also discussed briefly.

Low Sexual Desire

Recent data from the Global Sexual Attitudes and Behaviors Study (GSSAB; Laumann et al., 2005) suggest a prevalence rate for low sexual desire (also called HSDD) somewhere between 13 and 28%. Several other studies report rates ranging from 0 to about 25%, depending on the nature of the question, the population sampled, and whether the individuals were clinically or self-diagnosed. Taken together, these and other studies (Lewis et al., 2010) suggest a prevalence rate of somewhere between 15 and 25% of men, with higher levels in men over 60 years. With respect to sexual desire, it is important to distinguish between sexual 'desire' and 'interest'. Desire is presumed to be internally driven and physiologically based (at least for men), whereas interest is a more inclusive term that may be affected by such factors as partner attraction, relationship issues, environmental stressors, and so on (Rowland, 2012).

Risk factors related to HSDD in men are often biological and sometimes related to endocrine abnormalities. For example, low levels of androgens, testosterone in particular, are most commonly implicated in low sexual desire. In men, androgens decline with aging, gonadal (testicular) dysfunction, high prolactin levels, and various pathophysiological conditions. A relevant factor is not just the overall level of testosterone circulating in the blood, but the availability of that testosterone (called 'free' testosterone because it is not bound to molecules that prevent it from being biologically active) to exert an action on neural structures.

Sexual desire, as powerful as it is at times, exists within a hierarchy of biological and psychological needs. When other needs are not being met (usually a condition that induces stress), sexual desire often wanes. Thus, general life stressors such as disease, depression, psychobehavioral problems, and crisis typically result in low sexual desire – in such instances the HSDD is secondary to another (primary) condition, indicating that treatment of the primary condition will likely ameliorate the low sexual desire.

Relationship and partner issues sometimes play a role in low sexual desire in men – for example, a man's partner may have a sexual problem (e.g., anorgasmia or pain during sex) or an aversion to sex, or the man may not find his partner sexually attractive. Such conditions may result in low sexual interest, which may appear as low sexual desire. However, such men often find other sexual outlets and therefore the low interest is directed toward a specific partner or situation. That is, sexual desire may be normal, but interest in the partner is diminished or absent. Relationship therapy involving better communication between partners, an expanded repertoire of sexual behaviors, specified sex 'dates', and rekindling sexual interest may help overcome the problem, assuming the couple is motivated to work together to improve their sexual relationship.

Arousal Disorders

In men, the most common arousal problem is getting and keeping an erection, clinically referred to as erectile dysfunction (ED). Seldom do men have a problem feeling sexually aroused when they do have an erection – a disconnection between feeling aroused and being genitally aroused is more likely to occur in women.

ED is fairly common, affecting as many as 30 million American men and approximately 5–50% of all men depending on their age group (see Lewis et al., 2010). Because erectile response assumes well-functioning vascular and neural systems, the prevalence of ED increases with age, as these systems exhibit age-related diminished responsiveness. Thus, the prevalence may be as low as 10% in men under 40 years, with incrementally increasing prevalence to over 50% in men over 70 years.

What is not reflected in these numbers is the percentage of ED men whose etiology is primarily psychogenic rather than biogenic – recent epidemiological studies have not distinguished between the two. Obtaining such data would be challenging, given the overlap between categories and the often transient nature of psychogenic ED. However, the fact that the prevalence increases from a low of about 10% to as high as 50% in older cohorts (an increase that is primarily due to aging and thus biogenic factors) suggests that the prevalence of psychogenic ED is probably no more than 10% in the overall population (Rowland, 2012).

Risk factors may be broadly categorized into one of two domains: (1) pathophysiological, those arising from a general disease state; and (2) psychosocial, those arising from a negative affective state, most often related to relationship/partner and/or performance issues.

Pathophysiological Problems

Given that erection results from engorgement of blood to the penis, diseases or conditions that compromise cardiovascular function have the potential to interfere with erectile response. Furthermore, since vascular response is under the control of the neural system, neuropathy involving the autonomic nervous system may also interfere with erectile response.

- Diseases that affect cardiovascular and/or neural function are typically age related and sometimes fatal. Generally, then, as a biogenically based dysfunction, ED is not a specific disease process, but rather just one manifestation of a more general cardiovascular malfunction (Lewis et al., 2008). As a result, the common approach in the medical community is that a man having ED due to biogenic reasons usually has more significant health issues that require attention. Specific disease conditions likely to produce vascular-based ED include diabetes mellitus, hypercholesteremia, and hypertension, conditions that may result in part from particular long-term life style choices (e.g., smoking, lack of exercise, dietary preferences, and so on). Obesity is also a general risk factor for ED, although it is yet unclear if it represents an independent factor or whether its effect is tied to cardiovascular disease and diabetes.
- Neurogenic problems typically affect erectile response by interfering with autonomic pathways that allow dilation of vessels coursing to the penis, that is, the discrete neural control required to stimulate and control the smooth

muscle that allows increased blood flow to the penis is disrupted. Diseases leading to such erectile problems include Parkinson's, epilepsy, encephalitis, multiple sclerosis, and various other neural degenerative diseases. Strokes, accidents, brain and spinal injury, surgery, and other trauma, depending on their location, extent, and nature, may also affect erectile function either directly or indirectly. Trauma, for example, that directly affects the lower spinal cord is quite likely to disrupt erectile response.

Psychosocial Factors

The way people think, feel, behave, and relate to others can affect erectile response. In many instances, the psychological factors are related to general life events and therefore likely to affect erectile response only indirectly, for example, by attenuating sexual desire or arousal. But in other instances, these factors may be tied directly to concerns about getting an erection. Men having such concerns are likely to feel anxiety about their performance, to expect failure, to make behavioral adjustments such as trying to penetrate the partner in a semiflaccid state, and to overfocus on getting an erection – all strategies that can worsen the problem and interfere with positive dynamics within the relationship.

Currently, effective treatments for men with ED of any origin, biogenic or psychogenic, are available. A class of drugs called the phosphodiesterase 5-inhibitors (or PD-5i: Viagra, Cialis, Levitra, etc.), which increase blood flow to the penis, sometimes used in conjunction with brief sex education and counseling, can help men return to a more satisfactory sexually functional state.

Ejaculatory Disorders

Disorders of ejaculation are many – dry ejaculation, retrograde ejaculation, painful ejaculation, orgasmic anesthesia, and so on – but the most common and bothersome problems center on the timing of the event. Some men ejaculate very quickly because they are unable to delay it – a condition known as premature ejaculation; others have a difficult time reaching ejaculation or are unable to ejaculate at all – a condition known as inhibited ejaculation (IE).

Premature (Early) Ejaculation

Most studies estimate 10–30% of men experience PE at some point in their lives (Rowland, 2011). Variability in estimates arises from the use of different definitions, whether the estimate is based on clinical diagnosis versus self-report by the respondent, and the extent to which the man is sufficiently concerned about the condition to seek treatment – only about half the men experiencing PE actually seek help.

Although data are limited, estimates are that about 75% of men with PE have primary (or lifelong) PE (McMahon, 2002), and that the other quarter has acquired it at some point during their sexual lives. Acquired PE may result from either pathophysiological or psychological factors. About a third of men with PE also report having erection problems, so knowing which problem is primary and which is secondary (the ED or the PE) is important, as treatment needs to begin with the primary problem. Some research indicates that age is not a factor with respect to the prevalence of PE; other research, however, suggests that PE may either increase or decrease with increasing age. Given the inconsistent results, the most parsimonious position is to assume that there is no large change in PE prevalence related to age.

For most men with PE, no obvious pathophysiology exists; that is, no underlying problem in structural or functional anatomy, physiology, or biochemistry can be identified. When PE does have a pathophysiological origin, it is usually fairly easy to identify and is likely to surface during a medical history and examination. For example, among the conditions commonly associated with PE are lower urinary tract (such as prostatitis and urethritis) and endocrine problems, particularly hyperthyroidism. Sometimes, however, the site of the pathophysiology may be far removed from the pelvic or genital area; for example, cerebrovascular accidents have sometimes been linked to PE. Specific drugs may sometimes induce PE, although not necessarily with any reliability. For example, use of L-DOPA, pimozide (an antipsychotic used to control tics), amphetamine, heroin, and over-the-counter drugs that mimic sympathetic activation have on occasion been associated with PE.

Most current thinking views ejaculatory latency as showing 'natural' variation across individuals, suggesting some degree of 'hardwiring' of the ejaculatory reflex and latency. It is plausible that, as with most biobehavioral responses (e.g., eating and emotion), inherent differences in response tendencies exist and that, for the specific biobehavioral response of ejaculation, different men possess predispositions to respond with shorter or longer latencies. However, the actual inherent physiological properties that differentiate men with PE from men with more typical latencies are unknown.

Surprisingly little is known about psychological factors related to PE. The question whether men with PE are somehow fundamentally different from other men has long been a topic of interest. For example, several studies suggest that men with PE may have heightened social-cognitive or affective vulnerability. Specifically, anxiety, a construct considered central to many psychological disorders, has also been postulated to have a role in psychogenic sexual dysfunction, including PE. For example, men with PE on average display more trait- and situation-based anxiety and depression (Corona et al., 2004) than the general population. What remains unresolved is the reason or cause for the anxiety itself – whether it is genetically or developmentally predispositional.

Perhaps not surprising in view of the emotional characteristics and disturbances discussed above, one interpretation for the above associations is that heightened risk for affective problems, inhibited social confidence, and amplified impact of external influencers – including social norms and/or partner feedback – constitutes specific vulnerability in the realm of 'social-affective' functioning, at least for a subpopulation of men with PE (Rowland, 2012). Although the social-affective functioning of men with PE does not fall in the clinical range, this social-affective vulnerability may heighten the probability for developing and intensifying negative (and counterproductive) thought patterns – patterns known to contribute to, maintain, or exacerbate functional impairments in many psychological realms, including PE (Patrick et al., 2007).

More so than the other male sexual dysfunctions, PE is considered a couple's problem: the dysfunction does not typically exist outside the man's relationship with his partner. Thus, therapies often include both partners. In some situations, partner characteristics may also contribute to the problem, for example, when the partner has a sexual aversion, exhibits sexual avoidance, or is concerned about sexual pain. Although such partner issues may lead men to ejaculate rapidly, the PE in this case is actually secondary to the partner's dysfunction.

A number of treatment options are available for PE, including dapoxetine and off-label antidepressants – these drugs affect serotonergic function, thereby delaying ejaculation. Such medications may be used in conjunction with behavioral and cognitive therapies that reduce stimulation to the penis while concomitantly helping the man attend to the genital sensations that signal approaching ejaculation.

Inhibited Ejaculation

The prevalence of delayed ejaculation or IE (the latter being the complete inability to reach ejaculation) is unclear – normative data for defining the duration of 'normal' ejaculatory latency, particularly regarding the right tail of the distribution (i.e., beyond the mean latency to ejaculation), is essentially nonexistent. Furthermore, larger epidemiologic studies have not subdivided men into various types of diminished ejaculatory function. For example, the continuum (and/or overlap) from delayed ejaculation to IE has not been adequately explored.

In general, IE has been reported at fairly low rates in the literature, typically around 3–5%, and thus it has been seen as clinically uncommon. However, based on more recent clinical experiences, some urologists and sex therapists are reporting an increasing incidence of IE (Rowland et al., 2010) leading to newer estimates of anywhere between 3 and 10% (see Lewis et al., 2010). The prevalence of IE appears to be moderately and positively related to age – not surprising in view of the fact that ejaculatory function as a whole tends to diminish with age. However, no large-scale studies have systematically investigated the strength or reliability of this putative relationship.

- In some instances, a pathophysiological or biogenic condition may account for IE since any procedure or disease that disrupts sympathetic or somatic innervation to the genital region has the potential to affect ejaculatory function and orgasm. Thus, spinal cord injury, multiple sclerosis, pelvic-region surgery, severe diabetes, and medications that inhibit α-adrenergic innervation of the ejaculatory system have been associated with IE. Nevertheless, a sizable portion of men with IE exhibit no clear somatic factors that account for the disorder. As the result of their inability to ejaculate, these men also do not experience orgasm.
- Multiple psychosocial explanations have been offered for IE. In some instances, the man may have a strong 'autosexual' orientation that involves an idiosyncratic and vigorous masturbation style – carried out with high frequency – which does not 'match' vaginal stimulation. In other instances, disparity between the reality of sex with the partner and the sexual fantasy (whether or not unconventional) used during masturbation is another potential cause of IE (Perelman and Rowland, 2006). This disparity may involve multiple factors, such as partner attractiveness and body type, sexual orientation, and the specific sex activity performed. In summary, high-frequency idiosyncratic masturbation, combined with fantasy/partner disparity, may well predispose men to experience problems with arousal and ejaculation, resulting in the lack of sufficient psychosexual arousal during coitus to achieve orgasm.

Finally, the evaluative/performance aspect of sex with a partner often creates 'sexual performance anxiety' for the man, a factor that may contribute to IE. With respect to IE, anxiety surrounding the inability to ejaculate may draw the man's attention away from erotic cues that normally serve to enhance arousal. Some such men may be overconscientious about pleasing their partner and lose focus on arousing stimuli (Apfelbaum, 2000).

Few medical interventions exist for men with IE, although a number are currently under investigation. Assuming an etiology that is not biological, effective treatment often involves working with the couple to identify strategies to heighten sexual arousal in the man with IE.

Sexual Pain and Aversion Disorders

Sexual pain disorders in men (male dyspareunia), especially when genital related, are uncommon and most often secondary to a biomedical condition. Estimates for sexual pain in men have been reported at rates of 1–6%, but the reliability of such estimates is not yet established (Lewis et al., 2010). To further complicate matters, DSM-5 has now combined male and female pain disorders into a single category referred to as genitopelvic pain/penetration disorder. Genital lesions and abrasions (sometimes from surgery), prolonged erection after sexual stimulation has subsided (priapism), and pelvic trauma are sometimes sources of discomfort during sex. Insofar as sexual pain is related to an identifiable somatic cause, the prognosis for treatment is very good, assuming the source of the pain can be controlled.

Sexual aversion disorder (SAD) represents more than merely a lack of sexual interest or desire, but is characterized by a strong dislike of sexual intimacy and activity, including the sight, touch, smell, and other sensory aspects of sex as well as intercourse itself. In some instances, different aspects related to sexual intimacy may be differentially affected. Sexual aversion is often manifested through strong negative emotional responses such as disgust and revulsion. As with sexual pain disorders, sexual aversion leads to avoidance of sexual intimacy, but the reasons for this avoidance are quite different for each problem.

Due to the rare occurrence of SAD and the subsequent dearth of research on the problem, reliable prevalence rates are not available. A change in the conceptualization of this disorder is reflected by the fact that it has been removed from DSM-5. Furthermore, because such problems tend to be highly idiosyncratic, treatment is typically more complex and may involve combination therapies that include antianxiety medication and sexual counseling.

Epidemiology of Women's Sexual Dysfunction

In this section, risk factors and prevalence rates for disorders of desire, arousal, and orgasm in women are reviewed and pain disorders are briefly discussed. The prognosis and treatability of each dysfunction are also addressed.

Low Sexual Desire

Prevalence rates for low sexual desire (also called HSDD) in women are significantly higher than for men. The DSM-IV-TR does not define HSDD in a gender-specific way, despite apparent gender differences related to desire. Revisions in the DSM-5 address this issue by combining desire and arousal issues in women (only) into a single category, now referred to as female sexual interest/arousal disorder.

Data from the GSSAB (Laumann et al., 2005) suggest prevalence rates for HSDD somewhere between 26 and 43% in women, in contrast to estimates between 13 and 28% in men. In fact, HSDD probably has the highest prevalence rate among the female sexual dysfunctions, not surprising given the correlation between HSDD and other impairments in sexual functioning. One review of studies found that 64% of women indicated low sexual desire as the cause of any sexual problem (Hayes et al., 2006). However, it is not clear whether and by how much prevalence rates might change, given more recent conceptualizations of sexual desire in women.

Risk factors implicated in HSDD are biological, psychological, and contextual. As with men, low androgen levels may be related to low sexual desire in women. Other sexual dysfunctions may be related to HSDD, as impairment in the other phases of sexual response can impact subsequent desire. Psychological factors include affective disorders and sexual attitudes. Specifically, depressed mood and anxiety are correlated with higher rates of HSDD, as well as the antidepressants used to treat them (especially selective serotonin reuptake inhibitors). A woman's self-reported 'importance of sex' has been associated with desire; women for whom sex is very important are likely to have higher sexual desire. Finally, relational risk factors include relationship problems or poor relationship quality, both often leading to low sexual desire, or a large discrepancy in desire between partners.

Treatment for HSDD may include androgen replacement therapy for women experiencing androgen deficiency. Relationship therapy is often necessary, given that women with desire difficulties are generally in relationships and experiencing distress because their lack of desire is troublesome to them, their partners, or both. The most widely used psychological treatment for HSDD in women is sensate focus therapy, developed by Masters and Johnson (1970), in combination with other approaches. Sensate focus helps the couple learn to enjoy pleasurable sensations while decreasing the focus on goal-directed sex. As part of this approach, women educate their partners on touch and positions which stimulate desire, arousal, and potentially orgasm.

Arousal Disorders

The DSM-IV classification and definition of arousal difficulties in women, referred to as female sexual arousal disorder, has presented several challenges in assessing prevalence. First, cases in which lack of arousal could be attributed to another sexual dysfunction and/or that resulted from the physiological effects substance, medication, or a general medical condition did not qualify as a dysfunction (American Psychiatric Association, 2000). For example, the primary problem of low sexual desire could contribute to a secondary problem of lack of arousal. Although changes in arousal related to menopause are not considered a general medical condition, they may affect genital tissue thickness and elasticity, as well as lubrication. Second, a woman could be experiencing arousal difficulties due to inadequate stimulation, yet few prevalence studies investigated this parameter. Third, the definition dealt only with problems related to physiological response (e.g., adequate lubrication or vaginal swelling) and did not include subjective feelings of arousal.

As previously mentioned, difficulties with interest and arousal in women have now been combined into a single category in DSM-5, addressing many of the challenges related to diagnosis and assessment of prevalence. This new category and definition includes criteria for both subjective and physiological arousal. It also eliminates the need to differentiate whether the primary problem lies with interest or with arousal, as the two were often interdependent.

The range of women reporting problems with lubrication is between 3 and 31%, depending on the time frame used and the age of respondents (Graham, 2010). One review found prevalence rates between 8 and 15% for all women and 21 and 31% for sexually active women (Lewis et al., 2004), with 21% indicating experiencing distress due to these difficulties. It appears that these problems increase with age.

Several pathophysiological or biogenic conditions may account for physiological sexual arousal difficulties in women. Given that estrogen plays a role in maintaining vaginal tissue function and structure, estrogen deficiency has been associated with decreased or delayed vaginal lubrication and vaginal blood flow in postmenopausal or ovariectomized women. Disruptions to the sympathetic nervous system, which plays an important role in genital arousal, have also been implicated – thus conditions such as spinal injury and multiple sclerosis are associated with arousal difficulties. Other medical conditions disrupting arousal function include those that are endocrine related, such as hyperprolactinemia, diabetes mellitus, bilateral ovariectomy, and hysterectomy. Also included are cardiovascular problems such as coronary artery disease and hypertension – more often implicated in male ED but also factors in arousal difficulties in women (Salonia et al., 2006; Meston et al., 2008).

Psychosocial factors related to arousal difficulties in women include marital or relationship dissatisfaction, depression and anxiety (more so 'state' than 'trait' anxiety), interfering thoughts, and negative self-focus including poor body image (Bradford and Meston, 2006). Finally, a history of sexual abuse can contribute to arousal difficulties, as the sensations experienced during sexual activity may actually inhibit arousal.

Few medical interventions are available to women with arousal difficulties; in contrast with their effects on erection in men, vasodilating drugs (such as Viagra) tend to show inconsistent or only small effects (Meston et al., 2006). The EROS

clitoral therapy device (Urometrics, St. Paul, MN, USA), which uses suction to increase vasocongestion, has shown some success in increasing vaginal lubrication, sensation, and orgasm (Meston et al., 2006). Psychological treatments for female arousal difficulties include sensate focus, systematic desensitization, cognitive–behavioral techniques, and communication training.

Orgasmic Disorders

Disorders of orgasm in women, clinically referred to as female orgasmic disorder (FOD), are characterized by delayed or inhibited orgasm. The orgasmic difficulty persists despite a normal sexual excitement phase. Therefore, women who experience problems with orgasm, but who also experience difficulties in desire and/or arousal, would not be diagnosed with FOD. Rather, problems with arousal or desire would be considered the primary diagnosis, with the anorgasmia secondary to these diagnoses. Diagnosis of an orgasmic disorder is also complicated by the variability of the stimulation that can trigger an orgasm and the subjectivity of the experience of orgasm in women, in contrast to men, who generally reach orgasm with ejaculation (Meana, 2012).

Prevalence rates of about 24% have been reported for women with orgasm difficulties, making it the second most commonly reported sexual problem (National Social and Health Life Survey; Laumann et al., 1994). Risk factors for orgasm difficulties are most often psychological. Relationship problems (including conflict and lack of intimacy), anxiety, and obsessive–compulsive tendencies are commonly associated with orgasm difficulties (Meston et al., 2008). Interfering thoughts and worry during sex can also contribute to the problem. Because women often blame themselves for their sexual inadequacies, the anxiety and subsequent difficulties may become self-perpetuating (Meana, 2012). Finally, women generally experience a decrease in frequency of orgasm due to normal, age-related declines in sexual functioning.

Given the presumed psychological nature of FOD, no medical treatments have been found. Relationship and sex therapy may be beneficial in improving relationship quality and addressing inadequate stimulation contributing to the problem (Meana, 2012). One of the most widely used treatments for orgasm difficulties is directed masturbation, which uses cognitive–behavioral techniques to help a woman become familiar with her body and bring herself to orgasm, after which time her partner may become involved in the process (Meston et al., 2004).

Sexual Pain and Aversion Disorders

Although sexual pain is not uncommon among women, it is not well understood and DSM-IV-TR diagnostic categories did not adequately consider their complexity and diversity. In fact, the two classifications of sexual pain disorders in women – dyspareunia and vaginismus – are not reliably differentiated from one another. Dyspareunia is defined as recurrent or consistent genital pain, while vaginismus is defined as recurrent or persistent involuntary spasm of the musculature of the outer third of the vagina (American Psychiatric Association, 2000). The new DSM-5 definition has combined all pain disorders for males and females into one category – genitopelvic pain/penetration disorder – addressing this difficulty in differentiation. However, both the DSM-IV-TR and DSM-5 definitions specify that the pain interferes with sexual activity, although women may well experience genital pain in the absence of sexual activity. Genital pain in women may better be conceptualized as a condition lying on a continuum – from sexual to nonsexual – taking into account various aspects of the pain itself, as well as psychological and contextual factors (Farmer et al., 2008; Meana, 2012).

Given the ambiguity in definitions of sexual pain disorders in women, prevalence rates are difficult to determine. Ranges between 12 and 39% have been suggested for premenopausal women experiencing sexual pain. One study that distinguished the two DSM-IV-TR disorders found a rate of 5% for vaginismus and 28% for dyspareunia, while studies from North America have found a rate of 12% for dyspareunia (Farmer et al., 2008). A study assessing different types of pain symptoms found subgroups and an overall lifetime incidence for sexual pain of 16% (Harlow and Steward, 2003). It is unclear whether prevalence rates vary with age.

Several biomedical risk factors have been correlated with female sexual pain. Frequent or persistent vulvar and/or vaginal infections have been associated with dyspareunia, as has vaginal atrophy (Farmer et al., 2008). Estrogen may be indirectly involved, as women who are taking oral contraceptives, are pregnant, or are in the periovulatory phase of their menstrual cycle have reported increased genital pain. In addition, postmenopausal women with reduced estrogen levels have reported vaginal atrophy, vaginal dryness, and dyspareunia (Farmer et al., 2008). Tissue damage resulting from abdominal or pelvic surgeries or sexual trauma may also lead to female genital pain as do vaginal spasms or contractions (referred to as pelvic floor hypertonicity) and weak pelvic muscles (Reissing et al., 2004). Few psychological risk factors have been identified, but factors such as catastrophizing and hypervigilance may exacerbate an existing condition (Farmer et al., 2008; Meana, 2012). Generally, however, genital pain and affective disorders have been only weakly correlated; it may be that the distress caused by the genital pain contributes to feelings of sadness or anxiety.

The prognosis for pain disorders in women is poor, especially if left untreated, as the problem may worsen due to tissue damage and irritation from continued sexual activity. Fear of the pain itself may intensify the problem (Meana, 2012). Although well-designed treatment studies are sparse, for one subtype of dyspareunia, vulvar vestibulitis syndrome, surgical removal of painful vestibular tissue appears effective (Farmer et al., 2008). Electromyography biofeedback and cognitive interventions may help with the pain catastrophization and hypervigilance, such that women redirect their thoughts away from the sensations and concern about pain. Given the complex and emotional nature of pain, a multidisciplinary approach relying on both medical and psychological interventions may yield the best outcomes (Farmer et al., 2008).

SAD is characterized by a persistent or frequent strong aversion to or avoidance of sexual activity with a partner.

Although categorized under the disorders related to sexual desire in DSM-IV-TR, there have been questions as to whether it truly falls within this category, as women presenting with SAD rarely express concern over their lack of desire (Meana, 2012). Rather, they are more likely to express disgust, fear, or anxiety over engaging in sexual activity. Thus, it is unclear as to whether SAD represents an actual sexual dysfunction or whether it might be better conceptualized as a specific phobia.

Prevalence rates for SAD remain largely unknown and, as with the analogous condition in men, DSM-V has now removed this classification. Nevertheless, clinical observations suggest that the prevalence for SAD is higher for women than for men. In addition, the prognosis for SAD is poor. If conceptualized as a phobia, treatment typically focuses on reduction of fear and anxiety, thereby reducing interference with sexual activity but not necessarily resulting in more enjoyable sex (Meana, 2012).

Summary and Conclusions

The past two decades have witnessed significant strides in understanding the prevalence, etiology, and treatment of men's and women's sexual dysfunctions. Driven partly by pharmaceutical interests and resources, men's dysfunctions such as ED, low sexual desire, and PE have been the object of substantial research, the result being greater awareness of these problems, clearer detail of the etiologies, and improved treatment methods using both biomedical and counseling methods. Other problems such as IE and sexual pain and aversion disorders in men are only now beginning to receive attention.

Women's dysfunctions too have attracted significant attention over the past decade, with the development of new models of sexuality, greater clarity regarding the types of problems, and some moderately effective strategies for overcoming problems. Given that women tend to focus more on relationship issues than men when assessing satisfaction within their sexual relationship, biomedical interventions for sexual desire and arousal tend overall to be less effective, and relationship counseling figures more prominently in successful treatment. On the other hand, anorgasmic women are sometimes served well through self-exploration that includes educational and self-stimulatory components.

Finally, it is necessary to realize that the understanding and classification of sexual problems is far from an exact science. As sexual problems are better understood; as demographics change; as norms, attitudes, and definitions vary over time; and as better sampling methods are developed, prevalence rates are likely to be affected.

Sexual Harassment: United States and Beyond

Anna-Maria Marshall, University of Illinois, Urbana-Champaign, Urbana, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by V. Schultz, volume 21, pp. 13981–13987, © 2001, Elsevier Ltd.

Abstract

Beginning in the 1970s, women filed lawsuits in U.S. federal courts arguing that unwanted sexual attention at workplace constituted a form of sex discrimination. After decades of judicial policy-making, the legal definition of sexual harassment remains ambiguous, and the process for offering relief to targets of harassment reflects employers' interests in addition to employee rights. At the same time, sociologists and psychologists have explored the causes of employee's experiences with sexual conduct in the workplace and its impact on the targets. Social scientists have also analyzed organizational responses to sexual harassment, research that raises questions about how legal rights ought best be protected. This article examines sexual harassment law in the United States, and then turns to the social science literature that documents the frequency of harassment, employees' understanding of their rights and their willingness to file claims, and concludes by considering evidence of 'sexual harassment in the workplace' (rather than 'at workplace').

Legal innovation, particularly in the area of civil rights and civil liberties, emerges from the clash of complex social forces. Notably, social movements and advocacy networks make novel claims for the recognition of new rights on behalf of the powerless and the marginalized. These new rights might protect groups from discrimination or enhance their power in more political arenas. However, activists do not exercise complete control over the process or pace of legal innovation, particularly in the judicial arena. Rather, their opponents, who normally have greater resources, resist their claims. The end result is often a new set of rights that embodies the compromises inherent in this adversarial process.

Women and their lawyers followed this path of legal innovation when creating the right to a workplace free from sexual harassment, a development that began in the United States. In the 1970s, an interesting combination of feminists, lawyers, and individual women filed employment discrimination lawsuits arguing that unwanted sexual attention in the workplace constituted a discriminatory working condition in violation of federal employment discrimination statutes (Marshall, 1998). This new interpretation of these statutes generated resistance among employers, especially among their lawyers and human resource professionals. The resulting judicial precedents have generated definitions of sexual harassment that remain ambiguous, even after years of litigation. In addition, the remedies – and the conditions that attach to those remedies – reflect employers' interests as well as employee rights.

The development of the legal claim for sexual harassment in the US coincided with the recognition of many disadvantages women faced in the workplace. Many trace the origins of the concept of sexual harassment to Lynn Farley at Cornell University, who offered a field seminar on "Women and Work" (Elman, 1996; Cahill, 2001; Weeks et al., 1986). Relying on consciousness-raising as a pedagogical technique, Farley and her students realized that everyone in the class had been forced to quit or been fired from a job because of the behavior of male colleagues (Farley, 1978). The group described this experience as 'sexual harassment,' a concept that Farley developed in her book *Sexual Shakedown* (1978). That class gave rise to a small women's rights organization at Cornell, Working Women United, that conducted some of the first surveys of working women and that publicized the problem, getting national attention (Elman, 1996; Cahill, 2001; Weeks et al., 1986). In the late 1970s, larger, multiissue women's organizations in the US, such as NOW and 9 to 5, included sexual harassment on their agendas. They designed public education campaigns to raise awareness among working women and lobbied the U.S. Congress and administrative agencies to regulate workplaces. Later on, these organizations filed amicus briefs in prominent court cases in the US and occasionally supplied lawyers when interesting cases reached appellate courts (Marshall, 2001).

As the legal claim for sexual harassment has developed, sociologists and psychologists have generated a rich research tradition exploring women's experiences with sexual conduct in the workplace. They have identified several different explanations for such conduct and have documented the range of responses to such behavior. In addition, social scientists have analyzed organizational responses to sexual harassment, research that raises questions about how legal rights ought best be protected.

This article describes the origins of the legal claim for sexual harassment in the United States, emphasizing U.S. judicial precedents that define sexual harassment and that specify processes for redressing it. The article also outlines the social scientific accounts of sexual harassment in the workplace, demonstrating the way that law both corresponds to and deviates from employees' experiences. And finally, a brief discussion of the diffusion of sexual harassment laws to other jurisdictions suggests alternative conceptualizations of the harms that may offer new regulatory possibilities.

Defining Sexual Harassment in the US: Legal Rules and Workers' Experiences

Legislative and administrative policy-makers in the US were slow to take an interest in regulating sexual harassment, and not surprisingly, the claim found its way to the courts. Title VII of the Civil Rights Act of 1964 prohibited sex discrimination in

the terms and conditions of employment but does not specifically identify sexual harassment as a form of sex discrimination. The first cases articulated claims for *quid pro quo* harassment, where women's submission to sexual favors was a requirement of the job. At first, federal courts dismissed these cases, arguing that sexual harassment was a personal problem between men and women in the workplace that emerged from the 'natural attraction' of opposite sexes. Thus, this behavior was not a social problem that the judicial system ought to resolve (MacKinnon, 1979).

Federal courts in the US first recognized sexual harassment as a form of sex discrimination in a series of cases in 1976 and 1977 (*Williams v. Saxbe* 1976; *Barnes v. Train* 1977; *Tomkins v. PSE&G* 1977). The courts reasoned that sexual demands placed on working women were a working condition imposed on women but not on men. As such, they constituted sex discrimination. But the courts limited the claim to situations where supervisors explicitly made a promotion, salary, or the job itself contingent on sexual favors.

Later in the 1970s, women began filing lawsuits with more expansive claims, describing working environments rife with sexual jokes and banter, as well as unwanted physical contact that, in some extreme cases, constituted sexual assault. Unlike women making claims for *quid pro quo* harassment, however, these women did not lose their jobs or suffer any tangible job detriment like the loss of a raise or a promotion. Nevertheless, they argued that the working environment imposed a substantial burden on their ability to perform their jobs. Although these claims initially failed in court, the Equal Employment Opportunity Commission promulgated regulations in 1980 that defined sexual harassment as including behaviors such as jokes, threats, and demands for sexual attention when "such conduct [that] has the purpose or effect of unreasonably interfering with an individual's work performance or creating an intimidating, hostile, or offensive working environment" (29 C.F.R. Sec. 1604.11).

The U.S. Supreme Court endorsed these regulations in *Meritor Savings Bank v. Vinson* (1986), in which it defined a hostile working environment as a workplace where employees faced "unwelcome sexual advances, requests for favors, and other verbal or physical conduct of a sexual nature" (*Meritor Savings Bank v. Vinson* 1986, 65). The Court also articulated the standards for establishing a successful claim: "For sexual harassment to be actionable, it must be sufficiently severe or pervasive 'to alter the conditions of [the plaintiff's] employment and create an abusive working environment'" (*Meritor Savings Bank v. Vinson* 1986, 67). Later, the Court clarified that the behaviors had to interfere with the employee's performance of her job duties, although employees did not necessarily have to sustain severe psychological distress (*Harris v. Forklift Systems, Inc.* 1993). Thus, the legal definition of a hostile working environment had both objective and subjective components. The conduct in question had to meet a standard that was clearly objectionable, but the target of the harassment also had to perceive the conduct as being harmful.

The problems associated with linking sexual harassment to sexual conduct became apparent when courts started hearing cases involving same-sex sexual harassment. Given that the premise of the original holdings was that a male supervisor's harassment of a female employee constituted sex discrimination, same-sex harassment fit less comfortably within this legal framework. However, the Supreme Court resolved this question by holding that same-sex harassment violates Title VII as long as the plaintiff can prove the statutory requirements: that the harassment was severe and pervasive and that it was discriminatory (*Oncale v. Sundowner Offshore Services, Inc.* 1998).

The claim for sexual harassment was a novel judicial interpretation of a statute, illustrating the capacity of the courts to address social problems when those problems do not reach the agendas of other policy-makers. However, critics have noted the limitations of these court-crafted policies. Civil libertarians have observed that to avoid liability, employers might adopt restrictive policies that could unnecessarily ban all sexual expression in the workplace (Volokh, 1991; Schultz, 1998). On the other hand, feminists have argued that by tying the claim of sexual harassment to sexual advances, courts have misconceptualized the problem, which is actually more general male domination in the workplace (Abrams, 1997; Franke, 1996). And Vicky Schultz (1998) has argued that tying sexual harassment to sexuality ignored a wide array of other forms of harassment that had nothing to do with sexual advances.

Over the years, sociologists and psychologists have conducted extensive research on the nature and prevalence of sexual conduct in the workplace, offering a perspective on whether the legal definition corresponds to employees' experiences at work. According to most studies, women often face unwanted sexual attention in the workplace. Notably, women remain the primary targets of such behaviors (Uggen and Blackstone, 2004). Experts estimate that between 35% and 50% of all working women have had at least one such experience (Gutek, 1985; Fitzgerald and Ormerod, 1993; Fitzgerald et al., 1988). Still, more recent research has begun to explore sexual harassment of men (Settles et al., 2012; Kearney and Rochlen, 2012; Uggen and Blackstone, 2004) and sexual harassment between employees of the same sex (Bennett, 1996).

Sexual conduct in the workplace comprises a range of different behaviors that vary in their intrusiveness. To capture this range, researchers follow a particular protocol: they first ask respondents whether they have experienced specific sexual behaviors, ranging from crude jokes and remarks to sexual assault. They then ask respondents how often those behaviors occurred and what effect they had. Lastly, respondents are asked whether the behavior constituted sexual harassment (Fitzgerald et al., 1988; Fitzgerald and Ormerod, 1991). This research design allows researchers to examine not just the prevalence of sexual conduct in the workplace, but also the influence of legal rules on employees' perceptions of their own experiences (Marshall, 2003).

By far, the most common form of sexual behavior in the workplace was what Fitzgerald and her colleagues described as 'gender harassment' – conduct that conveys insulting or hostile views of women but which are not necessarily "aimed at sexual cooperation" (Gelfand et al., 1995). This conduct would not meet the objective standards set by the courts for sexual harassment because it is insufficiently 'severe.' The second category, 'unwanted sexual attention,' consists of behavior that is more explicitly sexual in nature, including uninvited conversations about a target's sex life or pressure for dates. If evidence showed that these behaviors were in some way welcomed by targets, they might be considered innocuous

flirtation; when unwelcome, such conduct is more intrusive and threatening to the target. The third category consists of 'sexual coercion' – demanding sexual favors backed by a promise of benefits or a threat of negative consequences. This category would be considered *quid pro quo* harassment in the courts (Gelfand et al., 1995).

Researchers have several competing theories to explain the existence of sexual harassment in the workplace. Some suggest, for example, that sexual harassment is "the product of culturally legitimated power and status differences between men and women" (Welsh, 1999; MacKinnon, 1979). Sex-role spillover theories emphasize the way that potent stereotypes and gender socialization processes extend male dominance over women into the workplace, making women vulnerable to sexual harassment (Tangri et al., 1982; Gutek, 1985). Women are most likely to be harassed in workplaces where the proportion of workers is skewed – either more females or more males – because in such locations, women's 'femaleness' is rendered more conspicuous (Stockdale, 1996; Welsh, 1999). In male-dominated work settings, masculine qualities of toughness and competition are valued more highly, and women's presence is threatening to that workplace culture (Vogt et al., 2007). On the other hand, in female-dominated workplaces, sex roles characterized by nurturing and connection drown out work-related identities (Gutek and Morasch, 1982). Thus, greater contact between men and women at work, particularly when men numerically dominate the workplace, is responsible for more sexual harassment (Gutek et al., 1990; Gruber, 1998).

Others argue that sexual harassment emerges from power differentials between men and women. In this view, sexual harassment is one byproduct of male economic power over women – a technique that men use to maintain that dominance (MacKinnon, 1979; Uggen and Blackstone, 2004). Extensive evidence of female supervisors being harassed by subordinates and peer harassment led some to question whether power was truly a factor in sexual harassment. Having less power in their workplaces, women are more likely to be harassed by both their coworkers (Gutek, 1985) and their subordinates than by their supervisors (McKinney, 1990, 1992; Rospenda et al., 1998). Researchers, however, argued that these forms of contrapower harassment simply reflect the extensive informal power that men have in the workplace (Cleveland and Kerst, 1993; Grauerholz, 1996). "[M]ale peers lack an institutional basis for dominating their female colleagues. For this group, sexual harassment may be one of the few means available for realizing this end" (Lafontaine and Tredeau, 1986). Similarly, characterizing sexual harassment as "an equalizer," McLaughlin et al. (2012) found that female supervisors were most likely to perceive their experiences as sexual harassment and to report such behaviors.

Women have different reactions to their experiences with sexual conduct in the workplace. For many women, such incidents can be devastating to their careers and well-being. Women report that as a result of sexual harassment, they suffer decreased morale on the job, increased absenteeism, and other negative changes in both the quality and the quantity of their work (Fitzgerald and Ormerod, 1993; Coles, 1986). Women also lose their jobs in the aftermath of these experiences, either by resignation, transfer, or even discharge (Coles, 1986; Fitzgerald and Ormerod, 1993). In addition to the work-related problems, targets can also suffer psychological damage because of sexual harassment. In clinical studies, victims report a series of symptoms – fear, anxiety, anger, and depression, for example – similar to those suffered by victims of sexual assault (Koss, 1990; Houle et al., 2011).

On the other hand, critics of this line of research argue that not every working woman reacts in a negative way to sexual expression in the workplace. For example, Christine Williams and her colleagues observed "Workers themselves often conceive of sexual behaviors at work along a continuum, ranging from pleasurable, to tolerable, to harassing" (Williams et al., 1999; Giuffre and Williams, 1994; Dellinger and Williams, 2002; Williams, 1997). For some workers, for example, sexual behavior and joking help to relieve stress (Quinn, 2002). Thus, contextual factors are likely to shape the impact of sexual conduct in the workplace (Williams, 1997; Williams et al., 1999).

Given the wide range of behaviors and the different reactions to those behaviors, it is not surprising that researchers have identified wide variation in targets' willingness to label conduct sexual harassment (Welsh, 1999; Fitzgerald et al., 1997). In most studies, women are more likely than men to label particular forms of conduct sexual harassment (McLaughlin et al., 2012; Uggen and Blackstone, 2004), although recent evidence suggests that men with more egalitarian gender beliefs are more likely than other men to describe behaviors as sexually harassing (Uggen and Blackstone, 2004). These assessments also depend on surrounding situational factors, such as the severity and frequency of the conduct and the status of the harasser (Stockdale et al., 1995; Giuffre and Williams, 1994; Marshall, 2003).

Organizational characteristics, formal policies, and legal rules also shape people's perception of sexual harassment (Tinkler, 2008; Marshall, 2003). For example, Tinkler analyzed people's perceptions of sexual harassment as a function of their familiarity with relevant policies as well as their own personal beliefs about the 'problem of sexual harassment.' She found that men who believed that people were too sensitive about sexual harassment and who had attended a training session were more likely than others to apply the label of sexual harassment to even less intrusive behaviors (Tinkler, 2008).

Sexual behavior at work has not disappeared in the years since sexual harassment was first recognized as a form of employment discrimination. Rather, sexual conduct and conversation remain fixtures of the American workplace. However, research has shown that employees do not automatically consider every such experience as sexual harassment. Rather, they reserve that label for more intrusive kinds of conduct that have a more harmful impact, in effect applying the objective and subjective tests suggested by the legal standards (Marshall, 2003). The next question is how employees choose to respond and how the legal environment shapes their options.

Sexual Harassment in Organizational Context: Grievance Processes in the US

The right to be free from sexual harassment is part of a package of civil rights that purportedly protect and advance equality in the workplace. In the United States, however, the target of the

harassment has the responsibility for enforcing those rights (Farhang, 2010). Courts have delegated authority to employers to design policies and grievance procedures either to prevent sexual harassment or to remedy it once it has occurred. As a result, sexual harassment policies have become relatively formal processes that mimic legal proceedings; they may do more to protect employers than to advance employee rights (Edelman et al., 1999; Marshall, 2005). This section examines sexual harassment policies developed in response to judicial precedent and describes research about how targets of sexual harassment navigate these processes.

Recent judicial activity on sexual harassment has focused on the grievance procedures surrounding employee complaints about harassing behaviors. The employer's grievance process was at issue in *Meritor Savings Bank v. Vinson*, in which the Court suggested that an appropriately designed policy could protect an employer from sexual harassment claims. Although Meritor had such a grievance procedure, it required employees to lodge complaints with their supervisors, which was unacceptable if the supervisor was the harasser. The Court noted that this process was fatally flawed, but that one might be designed that could protect the employer from liability for harassing conduct.

In later companion cases, *Faragher v. Boca Raton* (1998) and *Burlington Industries v. Ellerth* (1998), the Supreme Court provided further guidance about the kinds of grievance procedures that would protect employers from liability. The Court held that employers would be held responsible for their supervisors' harassing behaviors directed at employees resulting in negative consequences. However, in cases where the harasser took no 'tangible employment action' against his victim, the Supreme Court held that employers could defend themselves from liability when they had a proper sexual harassment policy in place and the harassed employee failed to use it.

Although the Court was vague about the details of the policies, human resources professionals and employment lawyers responded to the decision by developing policies that would meet employer's obligations under the new rules (Bisom-Rapp, 1998; Grossman, 2003; Edelman et al., 1999). Writing in professional journals, employment specialists narrowed in on a set of features for these policies that would inoculate employers from liability. For example, the policies had to define prohibited conduct, provide a list of specific examples, and be widely and regularly distributed to all employees and supervisors. The grievance process had to provide multiple avenues for pursuing grievances; it could never require a harassed employee to confront the harasser. Each complaint had to be investigated, even if the complainant was reluctant to pursue it. And finally, employers had to respond promptly to complaints and take corrective action to redress the problem (Grossman, 2003). These features largely addressed the Supreme Court's concern about the appropriate design for a sexual harassment grievance procedure.

In addition, the Court held that employers must show that they had 'exercised reasonable care' to prevent and redress sexual harassment. Human resources professionals urged employers to take the initiative in monitoring harassment. To demonstrate their proactive concern, employers increasingly adopted training programs to educate employees about the limits of acceptable workplace behavior and to teach supervisors about how to handle complaints brought to their attention. The evidence for the effectiveness of these training programs is thin (Tinkler et al., 2007; Tinkler, 2008, 2012). Still, courts have recognized that the adoption of these programs is evidence that employers are 'exercising reasonable care' in preventing sexual harassment (Edelman et al., 1999).

The Supreme Court's decisions in *Faragher* and *Ellerth* did not simply require employers to develop grievance procedures for sexual harassment. The Court also imposed obligations on employees to use the employer's grievance procedure before filing a complaint, or show a good reason why they failed to do so. Thus, if harassed employees "unreasonably failed to take advantage of any preventive or corrective opportunities provided by the employer," their complaints would be dismissed (*Faragher v. Boca Raton* 1998, 807; *Burlington Industries v. Ellerth* 1998, 765). The requirement of 'reasonableness' might have allowed some plaintiffs to argue that lodging complaints was not feasible given the surrounding context of the workplace – fear of job loss, peer pressure, or gender isolation, for example. Yet a study conducted after the decisions were released showed that each time a plaintiff failed to invoke a grievance procedure, the trial court dismissed the complaint (Sherwyn et al., 2001). Thus, the Supreme Court requires that to preserve their rights, targets of sexual harassment must do the one thing that they are least likely to do – use a grievance procedure to resolve their problems.

Through the years and across many different studies, respondents have reported that their first response is to try to ignore the behavior or to avoid their harassers (Merit Systems Protection Board, 1995; Blackstone et al., 2009; Marshall, 2005). When they do choose to respond, targets of sexual harassment have a wide range of options short of filing formal grievances. For example, they might engage in self-help by admonishing conduct they disapprove of, or they may seek support from their colleagues at work or friends and family outside the workplace (Blackstone et al., 2009; McDonald, 2012; Marshall, 2005). Yet these responses would not be enough to pursue a claim for sexual harassment in the courts. According to the standards the Court articulated in *Faragher* and *Ellerth*, targets must invoke their employers' grievance procedures to state a claim for sexual harassment.

Employees only very rarely use formal procedures to complain about their experiences with unwanted sexual attention (Firestone and Harris, 2003; Gutek, 1985; Fitzgerald et al., 1995; Welsh, 1999). Surveyed about their responses to sexual harassment, employees themselves described a variety of reasons for their reluctance to report their experiences. In general, they are ambivalent about the grievance procedures and the personnel who administer them (Marshall, 2005; Welsh, 1999; Fitzgerald et al., 1995). Employees reported three fears: losing their job, being blamed for the incident, or not being believed. Although many agree that sexual harassment policies have reduced the incidence of many forms of unwanted sexual attention (Gruber, 1998; Tinkler, 2008), survey research strongly suggests that employees have serious reservations about the very policy responses that are designed to protect their rights (Welsh, 1999; Marshall, 2005; Tinkler, 2008, 2012; Edelman et al., 1999).

These reservations reflect what employees know about their own workplaces: employment policies and procedures to

redress sexual harassment are firmly embedded in organizational practices and cultures. Thus, they may not be equipped to dismantle the structural problems giving rise to sexual harassment. Designed and implemented by managers, grievance procedures come to reflect the organization's interests, overriding their ostensible goal of protecting employee rights (Edelman et al., 1999; Marshall, 2005). Marshall (2005) demonstrated how, in one workplace, managers actively discouraged women from filing complaints, offering interpretations of underlying incidents that trivialized the harm or erecting barriers to complaints not contemplated by the policies themselves. Based on their own experiences and the experiences of others, the intended beneficiaries of these policies learned that the complaint process would be inhospitable to their claims and sought other, less formal means to address their problems.

Moreover, recent research suggests that sexual harassment policies may be having unintended consequences that could lead to backlash because of their complex impact on gender beliefs. For example, Tinkler and her colleagues showed that a sexual harassment policy triggered male-advantage stereotypes and led participants to think less of both their male and female colleagues (Tinkler et al., 2007). Participants exposed to such a policy found both men and women less competent, less considerate, and lower in status (Tinkler, 2008). Even the sex of the trainers may have an impact on gender beliefs. While female trainers in an experiment prompted men to express more egalitarian views of male and female competence, female trainers also triggered unconscious gender stereotypes among all participants (Tinkler et al., 2014). This line of research raises the very real concern that sexual harassment policies could trigger resistance (Tinkler et al., 2014; Kalev et al., 2006). By activating gender stereotypes that characterize women as fearful of sex and in need of protection, policies may have the unintended consequence of polarizing men and women in the workplace, which may also lead to backlash against all such policies (Tinkler et al., 2014).

The legal rules governing sexual harassment have shaped the U.S. workplace in meaningful ways. Most obviously, employers have complied with their legal obligations and adopted policies that define sexual harassment and provide targets with means for redressing their complaints. Yet by itself, law cannot dictate how these policies actually work. The legal definitions of harassing behavior remain ambiguous, depending on both objective standards of conduct and the target's subjective experience. Policies will not become relevant, therefore, unless a target perceives an experience as sexual harassment. And although the policies play an important role in employees' ability to vindicate their rights, the procedures are administered by managers who are chiefly concerned with protecting the employer's interests.

Sexual Harassment in Comparative Context

Cross-cultural research has demonstrated that sexual harassment is a common problem for working women around the world. Indeed, there are meaningful differences in the targets of sexual conduct at work in other countries, as well as in societal responses to such conduct. In addition, sexual harassment offers interesting insights into the process of policy diffusion. Other jurisdictions have relied on the United States as a model and adopted a discrimination framework as a means to address the problem, while other countries have forged their own solutions, drawing on their own cultural understandings of the causes and harms of sexual harassment.

For example, Uggen and Shinohara (Uggen and Shinohara, 2009) have analyzed the similarities and differences between women experiencing sexual harassment in the US and Japan. Women in both countries were most likely to meet with unwanted sexual attention in manufacturing industries and least likely to experience it in government work. Yet there were important differences. In Japan, the youngest workers reported higher lifetime rates of harassment, while slightly older women in the US reported higher rates of incidents. Uggen and Shinohara argue that this age effect is attributable to the timing of the introduction of the concept 'sexual harassment' in the popular culture. In addition, marriage and family rendered Japanese women less susceptible to harassment. Those effects disappeared, however, when the researchers factored in characteristics of the job. Notably, in Japan, higher income women were more likely to report sexual harassment. Uggen and Shinohara speculate that women with higher incomes work in male-dominated fields, making them more susceptible to this kind of attention.

Efforts to regulate sexual harassment are "refracted through the structure and culture of individual nations" (Uggen and Shinohara, 2009: 225). Kathrin Zippel (2006) has analyzed the processes of policy diffusion from the US to the European Union and its member states. Transnational advocacy networks were responsible for disseminating information about sexual harassment and for crafting proposals for possible regulatory frameworks. They persuaded the European Union to adopt 'soft law' measures – resolutions and recommendations to member states to develop their own policies against sexual harassment. Against this backdrop of 'Europeanization,' feminist officials in German policy-making institutions – 'femocrats' – placed sexual harassment on the political agenda. Feminist opposition to sexual harassment corresponded to trade union narratives about the exploitation of workers. As a result, the 1994 Employee Protection Act prohibited sexual harassment but did so as part of a larger package of employee rights. Similarly, feminist advocacy, policy-makers in Austria adopted the discrimination framework prevalent in the United States. However, the discrimination frame was not successful on the shop floor, where Austrian factory managers, for example, resisted implementing what they viewed as foreign forms of regulation (Cahill, 2001).

As in Germany and Austria, France has a long tradition of union-organized workplaces, and French activists preferred to portray sexual harassment as a violation of the respect and dignity owed to workers (Bernstein, 1994). Yet the French did not regulate sexual harassment as a work-related problem. Rather, sexual harassment is a crime in France (Saguy, 2003). These differences in conceptualizing the harm of sexual harassment offer opportunities to imagine regulatory frameworks that transcend the U.S. reliance on discrimination theories (Bernstein, 1994, 1997; Franke, 1996; Abrams, 1997; Schultz, 1998).

Conclusion

The legal innovation of recognizing sexual harassment as a form of employment discrimination offered women an opportunity to redress an obstacle to equality at work. Yet through the years, that opportunity has been filtered through the structure of the workplace and employers' efforts to protect that structure. The legal definition of sexual harassment has provided both employees and managers with a guideline for sorting behaviors based on the harm that they do, yet may be too limited to address the other forms of gender harassment that do not involve sexual conduct. Moreover, by giving employers authority for designing and implementing grievance processes, courts have limited the protection offered to protect employee rights.

Sexual Minorities and Sexual Citizenship

Abstract

The concept of sexual citizenship is based on the argument that citizens' rights and entitlements have long been influenced by issues of sexuality, including both heterosexual and same-sex forms. There have been major advances in terms of ensuring that gays and lesbians have access to the same sexual citizenship rights as heterosexuals. However, there are debates over whether sexual citizenship rights focused on same-sex couples still exclude and marginalize some others. There are also questions regarding whether Western concepts of sexual citizenship are applicable to other societies internationally.

The concept of 'sexual citizenship' draws on a broad view of citizenship that sees it as involving much more than just issues of nationality, or which passport a person is entitled to hold. Rather, the broader concept of citizenship is based on the view that being a citizen of a country also means that that country, and its government, should grant its citizens various rights and entitlements. These include the right to be protected from discrimination and the right of equal access to government services and welfare benefits. It is a conception of citizenship that goes back to at least the eighteenth century in Western thought. It has been particularly well developed in European-influenced conceptions of the welfare state, in which government is seen to have a central role to play in looking after the welfare of its citizens.

Nonetheless, the idea of what the rights and entitlements of a citizen should be, and the role of government in relation to them, has always been contentious. For example, many European countries have a broader view of the health and welfare benefits that a citizen should be entitled to, and the role of the state in providing them, than is the case in the United States. Even within Europe, social democratic parties have tended to favor a more extensive welfare state than conservative parties, although the influence of free market economics has led to a winding back of benefits in many countries.

However, it is not just the nature of what the citizen is entitled to that is contentious but also the issue of *which* citizens should be included or excluded from those rights and entitlements. Many of these disagreements have centered around the politics of identity. In other words, there have been debates regarding not just what the rights and entitlements of the majority of citizens should be but also regarding what the rights and entitlements of those individuals who belong to marginalized groups should be. So, for example, there have been struggles over whether women should have the same rights as men and over whether members of marginalized racial groups should have equal rights and entitlements to those of members of powerful racial groups.

Debates over sexual citizenship therefore need to be understood within this broader context of debates over what the rights and entitlements of citizens should be. But what is sexual citizenship? Conceptions of sexual citizenship have been seen by some commentators to cover a very broad range of issues pertaining to sex. In an early landmark article on sexual citizenship, Diane Richardson (2000) identified three aspects of sexual rights, involving (1) sexual practice (from the right to engage in same-sex relations to rights to sexual activity by the disabled), (2) rights of self-definition (e.g., the right to identify as gay or lesbian, or for women to have sexual self-determination and to control their reproductive rights), and (3) rights gained via social and political institutions (e.g., the right for same-sex couples or interracial couples to marry). Related issues include the rights of citizens who identify as transgendered, transsexual, and intersex (Evans, 1993) to have equal rights, access to medical services, and to have their identities legally recognized. Others see sexual citizenship as also including the rights of citizens to be protected from sexual exploitation, including the forms of exploitation involved in pornography and sex trafficking (Hearn, 2006).

However, contemporary political debates over sexual citizenship have been largely dominated by the issue of whether citizens in same-sex relationships should have the same rights and entitlements as citizens in heterosexual relationships. So, for example, Phelan (2001: p. 5) has argued that "lesbians and gay men are not currently citizens in the full political sense" in the United States in that they do not have the same rights to equal participation and equal protection as other citizens. Importantly, the concept of sexual citizenship does not just involve an analysis of the rights of sexual minorities. Underlying many conceptions of sexual citizenship is the recognition that mainstream constructions of citizenship have always involved the sexual (Bell and Binnie, 2000). As feminist political theorists have long pointed out (e.g., Okin, 1979), when modern democratic conceptions of the citizen were first being developed in the eighteenth century, they often revolved around the traditional conception of the citizen as a male head of household with female members of the family being constructed in a subordinate position. (The citizen was also generally constructed as white and property-owning). What many earlier feminist analyses did not adequately draw attention to was that the male head of household was therefore being constructed as predominantly heterosexual, given that this was a household conceived of in heterosexual family terms. Consequently, issues of sexuality lay at the heart of conceptions of citizenship but it was a conception of citizenship that excluded same-sex relationships. So, citizenship was traditionally constructed as 'heteronormative citizenship' (Johnson, 2002) – in other words, it was constructed in ways that assumed a heterosexual norm.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10224-7

The fact that the citizen (as a concept) was constructed as a heterosexual head of family draws attention to the ways in which citizenship has always traversed the public and private spheres. Given the foundations of citizenship in personal life, citizenship issues were not confined to the public sphere of economic and political life (Hearn, 2006) such as government, electoral politics, the market, or the workplace. Similarly, the concept of citizen has always been embodied via forms of gender (and race) as well as sexuality. Indeed, government policies in diverse fields, including welfare services, immigration, and military service have helped to construct modern identities of both the heterosexual and the homosexual (Canaday, 2009).

Initially, struggles over homosexual citizenship rights often reproduced a strong public/private division (Richardson, 2000). Debates over the decriminalization of male homosexuality in the West revolved around arguments that consenting adults should be free to engage in same-sex practices in private without risking criminal charges. Richardson and Monro (2012) have described this stage in the fight for equal citizenship rights as a struggle over mis-recognition; in other words, an argument that gays and lesbians should not be characterized as pathologically deviant (and, in the case of men, criminal). The right to engage in same-sex acts in private was a very limited form of sexual citizenship right, albeit a crucial one given the previous criminal sanctions in many countries. It was also a struggle that continued in many Western countries, such as some states of the United States, until relatively recently, although Britain had decriminalized homosexuality in the 1960s and France had abolished key sodomy laws as long ago as the eighteenth century. Nonetheless, homosexuality is still illegal in many other parts of the world, including parts of Asia and Africa (Tremblay et al., 2011).

However, especially following the decriminalization of male homosexuality in the West, broader issues of sexual citizenship increasingly came to the fore. Debates over the rights of gays and lesbians began to move beyond the right of the individual to be able to engage in sexual activity in private without the threat of criminal charges. They increasingly focused on additional rights, such as the rights of gays and lesbians to live free from discrimination and from homophobic violence. Antidiscrimination measures were successfully fought for in a range of countries, including South Africa and parts of South America (Tremblay et al., 2011). However, these struggles are ongoing even in some Western countries, for example, there is still not a federal antiworkplace discrimination policy in the United States and there are ongoing debates in Australia over whether religious organizations should continue to have exemptions from antidiscrimination legislation.

Increasingly too there were arguments regarding the rights of couples in same-sex relationships to have the same entitlements as those in heterosexual relationships. In other words, the gay and lesbian movement began to challenge heteronormative constructions of the citizen by arguing that same-sex couples should be recognized by the state just as heterosexual couples are and should therefore have the same entitlements as those heterosexual couples. The debates over government recognition also contributed to breaking down the public/private division in other ways as gays and lesbians increasingly argued that they should be able to live open lives, including displaying affection in public, rather than having to 'pass' as heterosexual in public and confining same-sex sexuality to the closet (Johnson, 2002). The late twentieth and early twenty-first century has seen major advances in many European countries, Canada, the United States, Australia, South Africa, and parts of Latin America (Tremblay et al., 2011) in terms of ensuring that same-sex couples can access at least some of the same rights and entitlements as heterosexual couples, although marriage still remains a stumbling block in many countries.

In other words, the gay and lesbian movement increasingly challenged the heterosexual construction of citizen identity and the resulting granting of rights, benefits, and entitlements to heterosexual couples only. (The potential problems that arise from largely accepting the couple as the basis of sexual citizenship will be explored later). The areas that can be impacted on by government recognition of same-sex couple relationships are extensive and range from issues of superannuation benefits and pensions, taxation, immigration, consent to medical treatment, welfare and health benefits, to family rights such as whether parenting relationships are recognized and to adoption rights. In the United States, it was estimated some years ago that there were an estimated 1049 federal rights and entitlements that heterosexual married couples could access, ranging from social security to employment benefits, that same-sex couples were not eligible for (Kotluski, 2004). Depending upon what rights and entitlements are granted to citizens in a particular society, sexual citizenship can therefore have enormous implications. These implications occur whenever government, or other relevant authorities, recognizes a sexual relationship for conferring benefits and entitlements. In some countries that only involves recognizing people in married relationships or in registered civil partnerships but in some other countries (such as Australia) it involves recognizing unmarried people who have lived together for a number of years.

So, sexual citizenship rights are far from an abstract issue. Sexual citizenship rights impact on whether you can marry the person that you love. If you fall in love with someone from another country, sexual citizenship rights can impact on whether you are able to bring your lover to live with you in your country. If couples can combine their incomes for taxation purposes, sexual citizenship rights can impact on the amount of taxation that you pay. If you die, sexual citizenship rights can impact on whether a surviving lover is eligible for a pension or superannuation benefits. Sexual citizenship rights can impact on whether you are able to give consent to your lover's medical treatment if they are too ill to make decisions for themselves or whether you are able to visit them in hospital. In the case of same-sex families, sexual citizenship rights can influence whether same-sex couples have the right to adopt or foster children, whether surrogacy arrangements are recognized and whether parenting relationships by nonbiological parents are recognized.

In other words, sexual citizenship has implications for a range of intimate relationships including both couple relationships and other forms of sexual intimacy. Consequently, sexual citizenship interacts with, and is indeed a form of, another version of citizenship that has been identified, namely, 'intimate citizenship' (Plummer, 2003; Roseneil, 2010). Intimate citizenship recognizes the relationship between citizenship and intimate personal relationships. However,

a difference between intimate citizenship and sexual citizenship is that the conception of intimate citizenship recognizes forms of intimate relationships, including caring relationships, that go beyond the sexual, for example, the relationships of friends, family, and extended kinship relationships. Sexual citizenship also impacts on emotional issues such as love. Consequently, sexual citizenship is a form of 'affective citizenship' (Johnson, 2010), in that it is a form of citizenship shaped by which emotions between individuals are recognized as legitimate by the state, for example, whether same-sex love is recognized. However, as is the case with intimate citizenship, affective citizenship also stretches beyond the sexual to include other forms of personal and public emotions. Consequently, what is distinctive about sexual citizenship, compared with other forms of citizenship, is the focus on the 'sexual' as a component of citizenship. Furthermore, while sexual citizenship can and does intersect with other forms of social marginalization such as gender and race (e.g., when lesbians are not seen to be sufficiently feminine or when black men are constructed as sexually dangerous to white women), the primary focus of 'sexual citizenship' is on the 'sexual.'

Note that the rights associated with sexual citizenship are not just economic and social, they also have cultural ramifications in terms of people's right to be recognized and represented symbolically (Bell and Binnie, 2000), not merely in mainstream political culture, for example, in the discourse of politicians, but also in the media and other forms of popular culture. Sexual citizenship rights can also impact on how people are treated in everyday life, for example, whether people are likely to be subject to homophobic abuse and violence. Here, as elsewhere, issues of sexual citizenship can go beyond issues of state recognition to include forms of social recognition, in terms of social attitudes and how people are treated in everyday life.

Critiques of Sexual Citizenship

While many gay and lesbian organizations internationally have seen the struggle for sexual citizenship as an important part of the struggle for same-sex rights (Tremblay et al., 2011), there are nonetheless a number of critiques that can be made of aspects of sexual citizenship. In particular, critics who draw on queer theory have expressed concern about the normalizing effects of sexual citizenship. After all, having the state recognize particular forms of relationships for the purpose of granting rights and entitlements can construct some forms of personal sexual relationships as the norm and others as deviant. In the process, state recognition can deny legitimacy to some of the diverse forms that same-sex sexual expression can take, including those that may be influenced by class and ethnic factors, and add to the pressures on those who are already stigmatized (Barrett and Pollock, 2011). Many queer critics have pointed out that governments have tended to only recognize marriage-like relationships that could be seen as mimicking traditional heterosexual relationships. As with same-sex marriage itself, the question therefore arises of whether granting sexual citizenship rights potentially marginalizes those gays and lesbians who engage in other forms of sexual relationships, for example, non-monogamous ones that involve multiple sexual partners or sexual relationships that are not long-term sexual partnerships (Butler, 2002). In other words, sexual citizenship rights could be the latest way in which the state constructs 'good' and 'bad' homosexual citizens (Smith, 1994), with only those homosexuals who ape heterosexual marriage relationships being constructed as 'good' homosexuals and others still being constructed as deviant and engaged in antisocial behavior. As Bell and Binnie (2000: p. 30) have put it: "given the heterosexualisation of Citizenship how can rights claims based on citizenship status from sexual minorities be made to work other than by replicating heterosexualized articulations of the 'good citizen.'"

It is not just that some forms of same-sex relationships are potentially privileged over others in ways that can exclude and marginalize non-marriage like relationships. Importantly, Richardson and Monro (2012) have noted that arguments based on the view that citizens who are in same-sex relationships should have the same rights and entitlements as heterosexual citizens can exclude transcitizens. Transgendered, transsexual, or intersex citizens do not fit into either same-sex or traditional heterosexual or gay and lesbian identity categories. Such negative outcomes do not surprise those queer critics who argue that conceptions of citizenship have always been exclusionary (Payne and Davies, 2012) because they were initially developed as ways of delineating national belonging from forms of racial 'otherness.' Furthermore, some proponents of broader forms of intimate citizenship would question the very focus on using sexual relationships as the constitutive feature of the unit of citizenship, pointing out that this can limit the state's recognition of other forms of intimate relationship which might be just as important as, or even more important than, sexual relationships in contemporary society, for example, close friendships (Roseneil, 2010).

In addition, left-wing commentators, whether drawing on queer theory or not, have noted the difficulties involved in trying to develop political strategies for advancing issues of sexual citizenship in a context in which both conceptions of the sexual and of citizenship are being commodified in capitalist societies. Such critiques include Evans' (1993) arguments regarding the way in which sexual identity has been reduced to a consumer choice lifestyle in a way that fragments political dissent and related analyses of the ways in which citizenship has been increasingly privatized under the influence of right-wing social and economic thought, so that benefits which were once delivered by the state are now seen to be obtainable only via the market (Berlant, 1997; Smith, 1994). Similarly, Stychin (2006: p. 913) argues that the recognition of the same-sex couple, via the United Kingdom's civil partnership scheme, involved the privatization of care to same-sex partners and the state reducing its responsibility accordingly. Consequently, those who are same-sex active but who do not engage in state-approved forms of sexual relationships, or who do not identify as gay or lesbian, or who lack necessary economic means, can be excluded from existing forms of sexual citizenship. The concept of sexual citizenship therefore remains a highly contentious one, partly because the very processes of inclusion that many see as a sign of major reform having been achieved can also involve redrawing citizenship boundaries in a way that excludes or marginalizes others. There are also issues regarding whether sexual citizenship as a concept can

adequately include the identities, experiences, and struggles of members of marginalized sexual groups living in diverse countries, especially those outside the West.

Are Western Conceptions of Sexual Citizenship Readily Applicable to Diverse Societies?

Bell and Binnie (2006) have pointed out that analysis of sexual citizenship has always involved having to engage with different geographies of sexual citizenship. As the earlier account suggests, it is difficult enough to give an account of sexual citizenship that covers Western societies given the differences between them. For example, it was noted that some European societies have a far more extensive conception of what the health and welfare entitlements of citizens should be, and the state's role in providing that, than in the United States. The state's forms of recognition of sexual relationships also differ markedly between countries, influenced by different institutions, cultures, and political histories (Smith, 2008; Tremblay et al., 2011). For example, in the United States, couples need to be married in order to access many federal entitlements (Kotluski, 2004). By contrast, in various countries, including some states of the United States, there are forms of civil partnership registration that make couples eligible for relevant government benefits. In Australia, both heterosexual and same-sex couples merely need to have lived together for a number of years in a *de facto* relationship, they do not have to be married for their relationship to be recognized for the purposes of federal government entitlements (Johnson et al., 2011). Similarly, countries have very different ways of recognizing parental relationships in same-sex families, if they do at all. So conceptions of sexual citizenship need to be sufficiently flexible to allow for differences in the ways in which particular countries have developed and constructed citizenship rights.

The situation is even more complicated if one tries to merely apply existing Western typologies and conceptions of sexual citizenship to nonWestern societies. There are potential problems in simply exporting Western concepts of sexual citizenship rights, based on particular assumptions about the respective roles of government and communities, to societies where there is not a clear division between the state and civil society. For example, the division between state and civil society is much less clear in societies from the Middle East to parts of Southeast Asia in which the sharia law operates and in which key legal decisions regarding personal relationships are made in religious rather than state courts. Similarly, in many societies, sexual behavior and expressions of identity may be 'policed' more by community groups, including forms of religious vigilantes in some extreme cases, than by agents of the state. Are these still 'citizenship' issues in same way as in the 'West'? They do still involve broader issues of social rights, or of social citizenship. However, they do not directly involve issues of state-based citizenship rights insofar as government has subordinated its rights to make decisions about such matters to religious powers. Similarly, it would be hard to establish that some issues seen as sexual citizenship issues in the West are sexual citizenship issues in societies where government welfare state entitlements are not so well developed and extensive – and where it therefore is not so easy to establish that state entitlements are being directly impacted by nonrecognition of same-sex relationships. At the least, conceptions and strategies of sexual citizenship used in the West would need to be extended and revised in order to cover such societies, the varying forms discrimination can take, and the diverse sites where political struggles can occur.

Even more fundamentally, Jeffrey Weeks (1999: p. 36) has suggested that the emergence of the sexual citizen is related to a now 'commonplace' development 'at least in the metropolitan heartlands of Western Societies' for members of previously marginalized sexual groups to claim an *identity* on the basis of that sexual identity and corresponding *rights* related to that identity. However, it has been argued that in some societies, such as China, sexuality may not be seen as being such a crucial part of identity as in the West (Chou, 2001). Though it should be noted that this is contentious since others would argue that sexual identity plays a more explicit role than Chou acknowledges in many 'Asian' societies, including Chinese ones (see e.g., Khor and Kamano, 2006). There are also questions about when it is appropriate to designate issues of citizenship as issues of 'sexual' identity as opposed to issues of gender identity. Some matters commonly considered to be 'sexual' in the West are also not necessarily designated in the same way in other societies. For example, Jackson (2001) has argued that some behaviors and attributes that would be constructed in terms of 'sexual' identities in the West can be understood better in terms of (multiple) eroticized 'genders' in Thailand. In other words, one's form of masculinity or feminity is seen to explain one's preference in sexual partners, with eroticism being understood 'as a secondary or derivative component' of one's gender identity (Jackson, 2001: p. 18). Similarly, Atluri (2012) cautions against assuming that Western conceptions of state-sanctioned rights of sexual citizenship can adequately encompass the identities, religious significance, or transgressive public performances of 'sexual' minorities such as Indian Hijras, or adequately address Indian traditions of transgressive sexual politics that involve conceptions of sexual renunciation and sacrifice rather than sexual activism.

Nonetheless, despite such reservations, sexual citizenship is increasingly taking on international forms. This is especially the case as there are increasing calls for same-sex issues to be seen as a crucial part of international human rights regimes, including via the United Nations (Clinton, 2011; Ki-moon, 2012). However, writers such as Atluri (2012) and Sabsay (2012) caution against constructing conceptions of Western superiority in regard to rights, especially ones based on conceptions of a vulnerable, sexually victimized, racial 'other' that needs to be liberated by Western interventions. After all, there is also a long history of Western colonialism, in which the rights of racial 'others' were repressed to ensure colonial rule. In particular, colonial rule often involved the imposition of Western laws outlawing homosexuality, including in societies where homosexuality had sometimes not been specifically criminalized before. Britain's notorious section 377 was imposed on various Asian societies that were part of the British empire, and still exists in India, Malaysia, and Singapore. Indeed, British colonial law also stigmatized Indian Hijras, reducing their traditional religious and social status.

At the least, trying to apply conceptions of sexual citizenship to diverse, non-'Western' societies draws attention to the need

to recognize the different ways in which citizenship is constructed, and the varied relationships between state and society that can exist in different parts of the world. However, it should be noted that there are nonetheless many parts of the world where at least some aspects of existing analyses of sexual citizenship analyses work well. This is particularly the case if one focuses on the heteronormative aspects of sexual citizenship, given the widespread nature of constructions of the citizen as implicitly heterosexual. There are also many parts of the world where the fight for the rights of sexual minorities, even if just for basic issues such as decriminalization of male homosexuality involves battles over rights that other citizens take for granted. Nonetheless, Western gays and lesbians need to respect the decisions of sexual and gender minorities elsewhere about whether they find struggles over 'sexual citizenship' to be the best way in which to formulate their own specific social and political aims. They also need to acknowledge that advances in gay and lesbian rights have not been confined to Europe or North America but have also taken place in countries ranging from South Africa to parts of South America (Tremblay et al., 2011).

The issue of the internationalization of sexual citizenship is further complicated by the fact that there are numerous transnational international sites where issues of sexual citizenship are both located and being contested. The United Nations has already been mentioned. However, as Hearn points out, these transnational sites also include the internet, which is a site where both marginalized groups such as gays and lesbians, are organizing to struggle for sexual citizenship rights, and where diverse issues of abuse of sexual citizenship themselves arise. The latter go far beyond same-sex issues to include, for example, issues involving child pornography or the sexual trafficking of women (Hearn, 2006).

Conclusion

Sexual citizenship has been a very contested site of political struggle, precisely because the sexual has been so crucial in constituting the unit of citizenship in most societies. As Richardson and Monro point out (2012: pp. 12–13), given the history of gays and lesbians being depicted as unnatural and a threat to society "for LGBT people to be recognized and accepted as 'ordinary citizens' who deserve equal rights suggests, therefore, that there has been a profound shift in the meanings attached to sexuality, gender and citizenship." That change has only been won because of long struggles by the gay and lesbian movement. This is not to deny that critiques of the normalizing, and potentially exclusionary, tendencies implicit in even the reformed versions of sexual citizenship have their point. However, given that the alternative is to leave sexual citizenship as heteronormative citizenship, that constructs the heterosexual as the norm, most gay and lesbian organizations (in the West at least) have decided that the benefits of ensuring the political recognition of same-sex relationships outweigh the potential disadvantages. Many theorists of sexual citizenship agree, arguing that the choice of remaining 'noncitizens' is not viable since it would involve harmful forms of exclusion and discrimination (Bell and Binnie, 2000: p. 146). Nonetheless, serious issues remain, including the need to ensure that conceptions of sexual citizenship rights include transgender, transsexual, and intersex issues. Finally, conceptions of sexual citizenship need to be flexible enough to cover the multiple ways in which citizen identities and entitlements, and relationships between the state and society, are constructed in different national, international, and transnational contexts.

Sexual Minorities in China

Day Wong, Hong Kong Baptist University, Hong Kong

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In postreform China, many sexual minorities have developed an awareness of sexual rights and a sense of belonging in a queer globality. However, as they are subject to the imperative of heterosexual marriage, sexual orientation and identity tend to be fluid and fragmented. The vast majority of sexual minorities enters heterosexual marriage, while some gays and lesbians have begun using the strategy of cooperative marriage. Despite decriminalization and depathologization of homosexuality, homosexuality remains stigmatized as it has been linked to HIV/AIDS, and married homosexual men are held responsible for spreading HIV to the low-risk population. Divisions among sexual minorities are witnessed along urban/rural and class lines.

Definitions and Prevalence

Sexual minorities are commonly defined as groups whose sexual identity, orientation, or practices differ from the majority of the surrounding society. In China where cultural prohibition against sexual minorities is strong and identity politics are not prevalent, it is difficult to draw an unequivocal dividing line between the sexual minority and the larger majority, nor can we know with certainty the size of sexual minorities.

Social science research on homosexuality in China has relied on descriptions of behaviors, desires, and attractions rather than sexual identities. The Sex Civilization Survey, the first nationwide survey of sexual behaviors, collected data from 20 000 subjects in China in 1998–99. Among the married respondents, 0.5% of the urbanites and 2.3% of the rural dwellers reported experiences of same-sex intimacy (Liu and Lu, 2005). The survey was implemented through official organizations and conducted in institutional settings. The response rate was very high, but given the sensitivity of the homosexuality issue in China, underreporting on same-sex relationships can be expected. Another nationwide random survey was carried out in 2001 with university students (Pan and Yang, 2004). To encourage fuller reporting of such sensitive issues, the survey relied on mailed questionnaires, with unidentifiable, return address typed envelopes provided to guarantee anonymity. Among the 961 respondents, 11.4% admitted different levels of homosexual orientation in a psychological sense and 17.6% reported experiences of having physical contact of a sexual nature with persons of the same sex. If being a homosexual is defined by both psychological and physical dimensions, 4.4% had both kinds of experience. Based on these surveys, official estimates of the homosexual population in China range from 2 to 4%. More liberal estimates would say around 7% if erotic same-sex hugging is taken as an indicator, or 11% if the psychological dimension is taken into consideration.

Questions can be raised as to whether those who have had a same-sex experience should be regarded as bisexual or homosexual. Among students who have psychological inclination, but not physical contact, 36.8 and 25.0% of the male and female groups, respectively, had experienced heterosexual sexual intimacy. Even among those who are homosexual in both the physical and psychological sense, 5.6 and 11.5% of the male and female groups, respectively, had experienced heterosexual sexual intimacy. The researchers remarked that rather than being exclusively homosexual, a substantial proportion of the students who had same-sex experience can be regarded as bisexual (Pan and Yang, 2004).

The tendency to have both homosexual and heterosexual experiences is not unique to university students. When looking at the more mature population such as married men, such tendency cannot be regarded as sexual exploration. Based on a 1998 survey, Zhang and Chu (2005) estimated that 70–80% of male homosexuals/bisexuals in the cities have married or will marry a woman. The proportion in the rural population can be as high as 90%. If sexual orientation is defined by sexual desire or attraction rather than sexual behavior, it is far from clear if these individuals are attracted to both sexes or obliged to live out the cultural prescription. In China where people consider it a moral imperative to marry, sexual orientation tends to be fluid and fragmented.

Family Obligations and Imperative of Heterosexual Marriage

China has undergone massive transformation from a command to a market economy since the reform in 1978. The loosening of state control in employment, commodities and the market has enabled Chinese people to enjoy unprecedented freedom. Young people in rural China have left family farming to look for employment opportunities in cities. Urbanites also experience a newfound freedom as a result of the decline of the work unit (*danwei*) system, which used to provide living quarters and food, approve marriage and travel, and exercise control over the lives of individuals. For many sexual minorities, geographical mobility, the emergence of the private housing market, and the market reform as a whole have enabled them to gain privacy and choice in intimate relationships. Living away from parents, being socially anonymous as part of city life, and having economic opportunities to make an independent living, all point toward the possibility of pursuing a sexual life away from the conventional norm of heterosexual marriage. In Western countries, the rise of industrial capitalism and its

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10247-8

resulting urbanization brought about similar opportunities, which enabled homosexual desire to coalesce into a personal identity. Individuals constructed their personal lives and social networks based on same-sex attraction (Weeks, 1977; D'Emilio, 1980/1993). In China, however, family pressure remains a major source of concern for sexual minorities.

With the retreat of the state in the provision of social welfare, the family has been looked upon as an indispensable unit of care. Motivated by the practical issue of how to care for an aging population, the Chinese government has reinvigorated filial piety, a core Confucian virtue. The Law on Protection of the Rights and Interests of the Elderly was passed in 1996 and the Chinese Filial Piety Awards Ceremony is held annually. Chinese sexual minorities do not simply observe filial piety out of compliance to state initiative. In an age of high mobility, fierce competition and unpredictable employment, the family serves as a collective of pragmatic, emotional, and symbolic importance. Parental support is relied on for educational attainment, establishment of social network, and career investment. The implementation of the one-child policy in 1979 has shaped the intergenerational relationship to be one characterized by emotional attachment rather than authoritarian parenting. Sexual minorities feel obliged to fulfill parental expectations in order not to cause them grief or shame.

When one reaches the age of marriage, parents and relatives are often keen to arrange meetings to introduce prospective partners. The intense pressure to marry is felt by most Chinese sexual minorities – the only child generation. Sons, in particular, bear the responsibility of having children and carrying on the family bloodline. The marriage status proves that one is a responsible adult, which saves the face of the parents and facilitates career advancement. Women are in no way better than men in escaping marriage pressure (Kam, 2013). Their freedom to move out of the parental home before marriage or relocate to another city is more restricted in comparison to men. The disadvantaged position of women in the job market and the gender income gap also make it difficult to gain financial independence outside marriage. Although popular media as well as scholars have used 'sexual revolution' to describe the changes in China, marriage remains the prevailing norm. Unlike those in the West who have delayed marriage or elected not to marry, the gap between the ages of first sex and marriage is small (Parish et al., 2007).

Based on ethnographic dialogs with over 520 homosexual males, Pan et al. (1995) found that those who were married gave reasons, which clustered around (1) believing that they must marry, otherwise they would be looked down upon by society, parents, and neighbors; (2) career advancement or leadership position in work units demands that one must be married; (3) their mothers want grandchildren; and (4) they fear old age alone. In the past, homosexual men buried their sexuality in (heterosexual) marriage. Such a strategy is now considered to be unethical and cause a great deal of pain to the marital partners. In China's sexual revolution, sexual happiness is regarded as the key to a harmonious conjugal family, which in turn, would promote social stability. Not only men but also women are entitled to enjoy sexual pleasure. The demand for an active and harmonious sex life leads to increased difficulties for homosexuals who opt to wed. In recent years, the problem of tongqi (wife of homosexual man) has been brought to public attention. It is estimated around 12 million straight women who are unknowingly married to gay men. Support groups have been established for these women, who suffer in a marriage that lacks love and sex.

In order to accommodate their same-sex relationships while minimizing direct conflicts with the family, some gays and lesbians opt for a cooperative marriage. Aided by the Internet, gays and lesbians are now seeking each other out for a public heterosexual marriage, so that they can pursue a same-sex relationship in their private lives. Cooperative marriage is often called 'fake marriage' (*jia jiehun*) or 'ritual/pro forma marriage' (*xingshi hunyin*). Some couples hold a marriage ceremony but do not apply for a marriage license. Other cooperative marriages can vary according to the living and financial arrangements, or the preference for children. Gays and lesbians who look for prospective partners on dating Web sites can discuss and agree on the terms of marriage. A gay newsletter published in 2008 reported that of the 100 respondents, 91% had learned about cooperative marriage, 24% were considering this option, and 20% had already opted for cooperative marriage (Chen, 2009).

The feasibility, strengths, and weaknesses of cooperative marriage are very much under debate. A study by Kam (2013) of the lesbian community in Shanghai showed that for some lesbians, marriage is the only way to move out from their parental home and escape parental control. They understand cooperative marriage as a compromise that fulfills parental expectations. Yet this conformity to the heteronormative model enables them to carve out space for their same-sex relationships. A cooperative marriage may develop as a household that welcomes other queer members for social gatherings. Hence, it has the potential of becoming an extended queer kinship network that includes the two same-sex couples as well as other community members.

Cooperative marriages are not void of the secular concerns found in any marriage. The fact that it is a performative union makes it liable to exemplify mainstream values. Gay men often prefer their marital partners to look feminine and pretty, thus tomboy lesbians are ruled out as a possible candidate. Many also expect their lesbian partners to have children through natural or artificial means. Lesbians require their marital partners to have a good job and own an apartment. Many refuse to consider gay men who are sissy or like to mingle in gay circles. Inequality, exclusion, and conflict are played out in the mate selection process of cooperative marriages. A study by Chen (2009) revealed that some lesbians fall in love with their marital partners in cooperative marriages. Their same-sex partners often feel excluded and jealous especially when lesbians have children with the marital partners and became more involved in the heterosexual families. Thus marriage and family life, which promise public recognition and security, can entice an individual away from the queer world.

Decriminalization, Medicalization, and Stigmatization

Many people believe that there is an increasing acceptance toward sexual minorities, by citing the evidence that homosexuality in China was decriminalized in 1997 and delisted as a mental illness in 2001. However, police intervention in the

activities of sexual minorities is common and sexual minorities continue to be the object of medical surveillance. As Kang (2012) pointed out, decriminalization of homosexuality in China should be understood as an unintended consequence rather than a sign of the victory of sexual rights.

In the Mao era and the early reform period, homosexuality was penalized under the category of hooliganism. The 1979 Criminal Law included forced sodomy and sodomy with minors as 'other hooligan activities' that undermine public order. Although the law did not mention consensual sodomy, the police regarded anal sex between men in both private and public as a type of general hooliganism that deserves arrest. Aside from the criminal penalty, homosexual men who are members of the Communist Party could be punished by having their membership removed. Nonparty members could lose their jobs, be detained without trial or sent to labor camps (Kang, 2012).

As the Chinese economic reform began to take root, legal reform was considered necessary to protect individual and corporate interests, and provide legitimacy for the government. The revised Criminal Law in 1997 emphasizes that all crimes must be expressly prescribed by the law, thus removing hooliganism for being an ill-defined, catchall crime. Sodomy with minors is prohibited under the criminal code of indecent assault. However, it is worth noting that the new law has no mention of forced sodomy between adults. This proves that the legal code in China is dominated by heteronormative assumptions and the issue of homosexuality has never been inside the purview of Chinese lawmakers (Kang, 2012).

The removal of hooliganism does not imply that sexual minorities in China are free from the oppression of the penal system. Aside from criminal law, they are subject to the Public Order Administrative Penalty Regulation. Homosexuals can face administrative penalties for engaging in prostitution, and group and public sex. When arrested by the police, they are often harassed, detained, and charged with fines. While sexual minorities in the United States face random street violence, their counterparts in China face police harassment. Police raids of gay bars, discos, and other establishments seem to be largely motivated by monetary gain, which indicates that the queer community is a victim of bureaucratic corruption.

Homosexuality is subject not only to legal punishment, but also to medical pathologization. Prior to 2001, homosexuality was classified as abnormal psychology and reparative therapy was carried out on some homosexual people. Academics and experts who published on homosexuality might express sympathy toward the suffering of homosexual people; yet they all tended to pathologize homosexuality and recommended scientific sexual education as the preventive measure.

The delisting of homosexuality as a mental illness by the American Psychiatric Association and World Health Organization, in 1986 and 1990, respectively, stirred up debates within the mental health professional community in China. In the *Chinese Classification of Mental Disorders* published in 1989 and 1994, homosexuality continued to be officially defined as a form of sexual disorder. The Chinese community of psychiatry saw itself as a doorkeeper to watch over the health of the national body and safeguard against the invasion of a decadent foreign culture. Although the majority in the field held that homosexuality was 'a strange disease that deserves denunciation,' nevertheless, opinions were diverse, which ranged from 'crime' and 'disorder,' to 'unclear' and 'natural,' and even to 'a matter of minority's oppression.' The continued efforts of activists in China and overseas, which include mobilization of support from the American Psychological Association and American Psychiatric Association, finally led to the removal of homosexuality from the list of mental illnesses by the Chinese Psychiatric Association in 2001 (Wu, 2003).

While the medical discourse in contemporary China no longer condemns homosexuality as a mental illness, homosexuality has been linked to HIV/AIDS, which are considered to be a sign of moral bankruptcy under Western influence. By linking homosexuality to AIDS, public discourses created social fear and reinforced the stigmatization of homosexuality. Chinese sexologist Pan Suiming (cited in Kam, 2013: p. 47) pointed out that AIDS prevention became the reason for the police and other authorities to harass and detain homosexuals. This situation is the result of the entrenched distrust held by legal authorities and public health professionals against homosexual people.

An increasing awareness of the AIDS threat in the 1990s caused Chinese officials, academics, and clinicians to pay attention to the specific population of men who have sex with men (MSM). The first survey on MSM in 1997–98 found that two-thirds of the respondents have never used condoms, half have engaged in intercourse with women, and one-third have been married. Due to the likelihood that HIV would not only spread among MSM, but also to the female population, the researchers warned that the spread of HIV in China may be faster than in the Western countries in the 1990s (Zhang et al., 2000).

Subsequent studies highlight the lack of knowledge and awareness of HIV risk among MSM and the role of public education in AIDS prevention. Other studies, nevertheless, showed that although many MSM have good HIV/AIDS knowledge awareness, high-risk sexual practices are still common and the rate of consistent condom use is low. It is necessary to examine the more deep-rooted cultural forces that shape one's decision to engage in protective practices. Prevention efforts can be hindered because of the stigma associated with homosexuality in the Chinese culture. To avoid exposure of their homosexuality, MSM were found to be reluctant to seek out health services or accept outreach services even though these are free of charge. In addition, the stigma associated with HIV/AIDS can cause further hindrance and lead to a low level of HIV testing.

More in-depth studies have been carried out on the stigma faced by MSM. A qualitative study by Liu and Choi (2006) with MSM in Shanghai found that the stigma faced can be traced to four cultural factors: social status and relationships, family values, perceptions of immorality and abnormality, and gender stereotypes of masculinity. Liu et al. (2011) examined the influence of both collectivism and individualism, which are both promoted in contemporary China, on the development of homosexuality stigma in an inequitable society. MSM who hold vertical collectivism tend to see the importance of social status, accept inequality, and conform to collectivist social norms. Consequently, they are more likely to perceive a higher level of public stigma. Presumably, MSM with an

individualistic orientation place self-interest above collective interest and disregard public attitudes toward their homosexuality. However, this does not apply to vertical individualism whereby individuals want to do their own thing and be the best. With aspiration for success and self-accomplishment, they tend to experience a higher level of self-stigma, that is, the fear of societal discrimination against them.

With regard to the rising trend of HIV infection, national HIV prevalence among MSM had increased from 1.4% in 2001 to 5.3% in 2009. In 2012, the prevalence rate was 6.4%, in which one in six living with HIV was infected through sex between men. While there is an increasing trend of infection among MSM, heterosexual sex takes the lead in transmission. In 2011, 52% of individuals newly infected with HIV reported heterosexual sex as the transmission route, and the prevalence among sex workers is very low (0.3%). However, since a substantial proportion of MSM are married or engage in intercourse with women, researchers reiterate that MSM/bisexual men can act as a bridge for HIV transmission to the low-risk population.

The participation of China in international health organizations requires regular reporting on the knowledge and spread of AIDS and other sexually transmitted diseases (STDs). This has led authorities, however reluctantly at first, to enlist the help of activists and nongovernmental organizations in collecting data about the (male) homosexual population. Government funds are granted to activists and academics for education, outreach, and research. While HIV-related organizations that serve MSM are flourishing, lesbian organizations are relatively invisible and limited by the lack of resources. Although lesbians also need to address the issues that threaten their health and well-being, their concerns are often overlooked by the government. Sometimes they share resources earned by MSM-related organizations to carry out their work. The state has thus unintentionally created queer-friendly institutions that provide support for sexual minorities (Zhou, 2009).

Sexual Identity, Cultural and Social Belonging

With the advent of the Internet, hundreds of lesbian and gay Web sites have emerged in China. Sexual minorities feel at home and that they are the 'natural' majority when they enter queer cyberspace. The cyberspace is particularly important for lesbians since traditional gay venues are highly commercialized and largely catered for gay men who have consumption power. The Chinese cyberspace enables lesbians to develop social networks and deal with real life problems associated with their sexuality (Martin, 2009). Although online commercialization is inevitable, which reinforces hedonist and individualist values (Ho, 2010), the Chinese cyberspace has enabled sexual minorities to express themselves and develop their sexual identities and communities (Wong, 2011).

The Internet makes connection possible between sexual minorities in China and their counterparts in other parts of the world. Although they may not be in actual contact with each other, some Chinese individuals have developed a sense of belonging in a gay globality (Martin, 2009). However, this does not imply a universal sense of sexual identity. On the one hand, self-conscious modern gay and lesbian individuals in China desire alliance with Western gay and lesbian networks and have subtly adopted Western identity politics. On the other hand, they reject Western dominance and seek to defend an authentic Chinese same-sex identity. The tensions of local/global, Chinese/West, and authenticity/modernity are played out in the paradoxical articulation of queer identity in China (Wong, 2007; Ho, 2010).

Sexual minorities in China call themselves *tongzhi* (literally, same will). 'Tong' (literally the 'same') refers to sharing the same political goal of subverting heterosexism while hinting at same-sex orientation. In recent years, the category has expanded to include lesbian, gay, bisexual, transgender, and queer-identified people. The creation of this label represents an attempt to indigenize sexual identity and reclaim a Chinese cultural identity. *Tongzhi*, which means comrade, was used as a term of address in communist China. The term has fallen out of common usage because of its revolutionary connotation and is now mainly used within the official discourse of the Communist Party. The appropriation by Chinese sexual minorities means a parodic political subversion (Bao, 2011).

The identity of tongzhi serves to connect sexual minorities in China, Hong Kong, Taiwan, and other diasporic communities. They have built a larger community of sexual minorities through networking on Chinese-language Web sites and the circulation of books and magazines. In the First and Second Chinese Tongzhi Conferences held in 1996 and 1998 in San Francisco and Hong Kong, respectively, the participants discussed issues that concerned ethnic Chinese sexual minorities. They asserted that confrontational politics in the West should be avoided as family relations and social harmony are of utmost concern to Chinese people. The coming home alternative was created as an indigenous model (Chou, 2000). Coming home emphasizes the process of introducing one's same-sex partner to family as a close friend, leaving the gay identity more unspoken. Parents may refer the partner as a second daughter or son, and the partner is integrated into the family.

In times of intense globalization, coming home and coming out can no longer be treated as opposing strategies. In 2005, Hong Kong activists joined the call to mark the International Day Against Homophobia and organized a rally. Three years later in 2008, the first pride parade was held in Hong Kong, and attracted hundreds of participants from the rest of China, Taiwan, and other regions. Even in these coming out events, the gaining of family acceptance continues to be a major theme, thus reflecting the cultural fusion of the coming out and coming home models (Wong, 2007). Shanghai followed suit in 2009 and held its pride festival every year but without a march, as demonstrations are heavily cracked down in China. In 2013, the first lesbian, gay, bisexual, and transgender (LGBT) march took place in more than 10 cities, although some organizers were arrested and detained.

A slogan in the march in Changsha stated: "No more homophobia, the world belongs to everyone" (*buzai kong tong; shijie datong*) and appeals to a Chinese utopia found in the Confucian Classic of Rites, *datong* (literally great togetherness), which has long influenced Chinese reformers and revolutionaries. The use of the notion of datong enables sexual minorities to claim cultural citizenship, the belonging to the Chinese culture. In China where queer desire has long been seen as either nonexistent or a foreign decadence, sexual minorities

reconstruct indigenous, historical accounts of same-sex relationships. Stories such as 'The Cut Sleeve (*Duan Xiu*),' which is about a Chinese emperor who cut his sleeve because he did not want to wake his male companion who was sleeping on it, and 'The Bitten Peach (*Fen Tao*),' which tells of an ancient ruler of a state who shared a bitten peach with his minister, are often cited as evidence that homosexuality was widely practised in China for thousands of years and had enjoyed wide acceptance. Female tongzhi communities circulated the anecdote about a group of women called rubbing mirror party (*mojing dang*), who were known for same-sex sexual practices and community bonding in late nineteenth-century Shanghai.

Today, *tongzhi* remains a popular identity label in China, but as a result of growing exposure to the transnational gay scenes, some individuals have come to adopt the westernized identity of gay. Some identify themselves in this way: "wo shi ge gay," which means, "I am a gay." Capable of using a mix of Putonghua and English, they are usually university educated, financially stable, middle class, and Internet users. They found that the English word 'gay' denotes happiness and is not as politicized and blunt as the term tongzhi. The use of a foreign term has been associated with an oblique, stylish, and westernized presentation of the self (Wong, 2011). Lesbians in China usually call themselves *lazi* or *lala*. These terms are abbreviations of the transliteration of 'lesbian,' which mark a hybridized discourse of sexual identities. There are still others who dislike the term tongzhi for being too politicized and the term gay for being too foreign. Some men describe themselves as *quannei*, that is, someone in the (tongzhi) circle. This enables them to build connections with each other and expand their social network without politicization of sexual identity.

Thirty years of market reform have increased the visibility of sexual minorities and opened space for diverse ways of negotiating sexual identity and cultural norms. Some people frequent gay venues and accumulate a collective identity as members of a certain homosexual group (*quannei*). In addition to the opportunities for cruising, these gay venues enable friendship development and a sense of social belonging. Others articulate a strong sense of sexual identity and sexual right. They resist heterosexual marriage and pursue an independent homosexual life. They call themselves 'pure gay' or 'pure tongzhi' to markedly distant certain sexual lifestyles, such as bisexuality or cohabitation with a woman (Sun et al., 2006). There are still others who adopt a heterosexual identity even though they enjoy same-sex encounters. They believe that heterosexual marriage is a social obligation, and avoids emotional attachment with same-sex partners. They perform only sexual penetration in same-sex activities, thus concurring to the desired gender role that informs heterosexual identity (Li et al., 2010). Sexual identity in contemporary China is fluid and fragmented, and it is not uncommon for individuals to switch back and forth from a heterosexual to homosexual identity depending on the context (Li et al., 2010).

Quality Citizens, Internal Divisions, and Transgender People

The emphasis on the cultivation of quality citizen–subjects has created division among tongzhi even though queer life in China includes queers from all over the world. The concept of quality (*suzhi*) originated in population control, which aimed to reduce population quantity and raise population quality. Quality refers to the physical, mental, and moral attributes of the citizen–subject that are necessary to ensure national survival. Quality has thus become a widely circulated currency in everyday language, which brings together notions of modernity, knowledge, hygiene, urbanity, wealth, and taste. It is used to exclude rural gay men, some of whom make their living through sex work and are called money boys. Money boys are a triply stigmatized identity, as a rural-to-urban migrant, a prostitute, and a homosexual (Kong, 2010). Quality tongzhi chastises money boys as outsiders who are uncivilized, dirty, and carry greater risk of HIV infection, which spreads to the urban community because of their greed and ignorance. They are considered the main culprits for shaming the entire same-sex community (Jones, 2007; Ho, 2008).

The concept of quality is also used by MSM as a tool to assess the risk of potential sexual partners, such as deception, theft and blackmail, and contracting HIV and STDs (Jones, 2007). Characteristics such as cleanliness, stability, and knowledge are associated with quality and low risk. Those who have attained a higher educational level and who have married are more desirable. Whereas in the West, desirability is granted to those who have come out in public, in China, it is more likely to be granted to those who enact the tongzhi identity privately, but publicly enact the identities of a good family man and a respectable citizen. Those who are unmarried and fully integrated into communities of practice of gay men are perceived to be promiscuous. The concept of quality encourages gay men to lead a double life and serves as a powerful normalizing force within the gay community.

Since China has not yet developed a full-fledged transgender community, transgender people are one of the most misunderstood minorities. Transgenders are still called renyao (literally, human monster) in everyday language. They are rejected by families and the larger society. Men who cross-dress are sometimes featured in shows and performances hosted in gay and lesbian bars. Yet, they feel marginalized and find it difficult to integrate into the tongzhi community. Pi Jun, in his autobiographical essay (2010), shared the experience of exclusion by both lesbians and transsexuals. Jun is a female-to-male transgender who has had a bilateral mastectomy. Since transgender people have a much lower visibility compared with lesbians and gays, and few related Web sites can be found, transgenders mingle with the lesbian groups. However, in recent years, some lesbian groups have refused to accept stone butch or female-to-male transgenders as lesbians. Pun felt that with a male self-identification, he did not belong in the two-step identification of lesbians in which first, I am a woman and second, I love woman. When he came into contact with other female-to-male transsexuals, he again felt excluded, as the transsexuals who underwent male reassignment surgery refused to recognize him as a real man.

The Chinese government claims a progressive attitude toward transgenders since policies have been adopted to grant them civil rights, allow them to change their identification cards, and legally recognize their marriages after sex reassignment surgery. However, Chinese transgenders have a much harder time in gaining social acceptance and personal freedom

than other sexual minorities. Unlike the official depathologization of homosexuality in 2001, gender dysphoria is considered to be first and foremost a mental illness. In 2009, the Chinese government published fairly stringent regulations for anyone who hopes to have sex reassignment surgery (http://shardsofchina.wordpress.com/2012/02/08/sex-in-china-the-third-sex-transgender-people-struggle/). For instance, they are required to live as member of the opposite sex for 5 years and undertake therapy for at least 1 year before such surgery can be considered. To protect marriage and family, the government refuses to grant married persons the right to sex change. Permission from their local police bureau must be obtained in order to confirm that they have no objections to the reassignment surgery and will issue an ID card to the individual for their new gender. These form multiple barriers for enforcing constraints over sex change. Even if successful, life afterward can still be unbearable since the gender on academic certificates and work permits has yet to change. Since the first sex change operation was carried out in 1983, only 2000 Chinese people have been able to become fully transsexual. For ordinary people, a successful transition is a next to impossible struggle, especially when the cost of surgery is estimated to be around 200 000 RMB (32 000 USD).

Conclusion

Unlike their Western counterparts who can live relatively openly as gay, encountering at worst religious opposition and chance of homophobic harassment, Chinese sexual minorities are subject to the imperative of heterosexual marriage. Sexual minorities in China have begun to call for the right to wed, which has met with some sympathy. Li Yinghe, an academic at the prestigious Chinese Academy of Social Sciences, has repeatedly proposed the legalization of same-sex marriages in the national committee of Chinese People's Political Consultative Conference. A famous Beijing activist–film director, Chun Tze Yan, argued that unlike Western individuals who do not hold marriage in high regard and frequently divorce, the Chinese value family and marriage, and that is why there is a strong and practical demand for same-sex marriage. The dual emphasis on gay rights and family values marks the specific character of tongzhi identity and politics.

Factors such as the marriage imperative, normative family obligations, desired gender roles, and the need for social and cultural belonging will continue to shape the formation of sexual identity and politics in China. What complicates the scene is the hegemonic discourse of quality, which causes division among tongzhi along urban/rural and class lines. The discourse of quality creates a system of hierarchy and domination grounded on distinctions between the respectable and the degenerate. Quality tongzhi are those who privately enact the tongzhi identity, but publicly perform the identities of a respectable citizen. Close integration with the gay community is associated with promiscuity, which would exclude them from consideration for cooperative marriages. To address internal divisions and exclusion will require the broadening of the queer political spectrum to more than just a fight for same-sex marriage.

Sexual Minorities in Modern Russia

Abstract

This article outlines the history of sexual minorities in modern Russia, beginning with a discussion of the methodological challenges posed by the interpretation of Western sources, on the one hand, and of Russia's discursive silence, on the other. The history of Russia's sexual minorities is divided into three historical periods: prerevolutionary Russia, Soviet Russia, and post-Soviet Russia. Special attention is paid to the differences between literary and other representations of homosexuality and the descriptions of gay and lesbian life provided in the diaries of Russian gays and lesbians, revealing a deep-seated ambivalence regarding the phenomenon of homosexuality in Russia.

Introduction

Writing the history of Russia's sexual minorities is a particularly challenging task given the fact that so many of the historical accounts were written by Western observers and that these accounts are highly subjective, shaped by the mutually defining nature of the relationship of Russia and the West that emerged in the sixteenth century, a relationship based on relatively limited contact. As Martin Malia comments, "Russia has at different times been demonized or divinized by Western opinion less because of her real role in Europe than because of the fears and frustrations, or the hopes and aspirations, generated within European society by its own domestic problems" (Malia, 1999: p. 8). Native Russian sources, on the other hands, are, in the words of Lloyd Berry and Robert Crummey, 'relatively laconic' (1968: p. xiv), and this is especially true in regard to sexual matters. Indeed, with the exception of the opening and closing decades of the twentieth century, Russians have maintained a discursive silence on the topic, which stands in stark contrast to the voluminous discourse on sex and sexuality generated in the West, described by Foucault in his 'repressive hypothesis.' That silence was reflected not only in the suppression and erasure of gay and lesbian voices but also in the absence of research into the lives of gays and lesbians in Russia that has left the topic of homosexuality in Russia especially vulnerable to Western interpretations that perhaps say more about the Western cultures that have generated them than they do about Russia itself. The following section provides a brief overview of the most influential of these Western interpretations.

The Western Gaze

Western accounts of sexual life in Russia from the Renaissance on display a marked tendency to view Russians as sexual libertines, which betrays an Orientalizing gaze that links an assumption of unfettered sexual behavior to economic and political underdevelopment and political autocracy. Some of the earliest accounts fall within this tradition. First-person accounts in the sixteenth century by Sigismund von Herberstein, ambassador from the German Empire to the court of Ivan IV, and by George Turberville, secretary to the English ambassador to Moscow, as well as the seventeenth-century accounts by Adam Olearius, a member of an embassy from the Duke of Holstein to Muscovy and Persia, insist that sodomy was a widespread practice among the Russians, and Olearius notes, "not only with boys but also with men and horses" (1967: p. 142), and that Russians bore little shame in regard to it. In fact, Olearius notes that these sexual escapades "provide matter for conversation at their carouses" (1967: p. 142). Turberville in a poem dedicated to his 'special friend Master Edward Dancie' describes the Russians as 'a people passing rude, to vices vile inclined,' and says the Russian peasant "will lead a bogard's (bugger's) life. The monster more desires a boy within his bed/Than any wench, such filthy sinne ensues a drunken head" (Cross, 1971: pp. 70–71).

Another important episode in the sexualization (and homosexualization) of Russia occurred in the context of the emerging science of psychoanalysis. Some of Freud's most famous clients were Russians: Lou Andreas-Salomé and Sergei Pankov. Freud diagnosed Pankov, better known as the Wolfman, as a repressed homosexual. Aleksandr Etkind argues that Freud viewed his Russian patients through the lens of contemporary Western stereotypes of Russians: "Sexual freedom was ascribed to Russians" (Etkind, 1997: p. 111). But Freud's patients were not the only source of this view. In 1912, a book was published in France *Confession sexuelle d'un anonyme russe* (The Sexual Confession of an Anonymous Russian), which was a first-person narrative of a Russian aristocrat who resorts to psychoanalysis in his struggle against pedophilic urges; and the rumors surrounding the tsarina's favorite, Grigorii Rasputin, were also of a decidedly sexual nature.

For many European leftists, Soviet communism promised to free individuals from the shackles of Bourgeois prudery and repression. The Austrian psychoanalyst William Reich and the Swiss journalist Ella Maillart saw early Soviet Russia as a kind of sexual paradise, where young people engaged in sexual relations naturally, with a total absence of shame. Reich later changed his opinion and in 1936 published an indictment of the repression of Soviet homosexuals. Similarly, André Gide, who traveled to Soviet Russia in 1934, was quickly disabused of any notion he might have had of Russia as a place of sexual freedom for homosexuals. He documented his disenchantment in his best-selling *Return from the USSR*. Nevertheless, the notion of Russia as sex friendly was picked up again during the Cold War by the historians John Lauritsen and David Thorstad (1974) who argued that the absence of legislation

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10218-1

criminalizing homosexuality in the early Soviet period suggested a tolerance for homosexuality. Simon Karlinsky mounted a vociferous attack against this interpretation of Soviet history in the San Francisco–based *Gay Sunshine Press*, tracing the homophobia of the Soviet regime to Lenin himself. Karlinsky offered an alternative sexual history of Russia, presenting prerevolutionary Russia as a kind of 'golden age' for gays and lesbians. In his zeal, however, Karlinsky made unreflective use of some dubious historical sources, such as Rozanov's *People of the Moonlight*, to argue for the homosexuality of medieval Orthodox saints, such as Boris and Gleb, and Moses of Hungary (1976: p. 1). The association of Russia with sexual freedom was resurrected once again in the late Soviet and early post-Soviet period by Western observers, such as American anthropologist Laurie Essig, American journalist David Tuller, and British novelist Duncan Fallowell, who found in Russia a sexually liberating, queer alternative to the West with its rigid conception of sexual identity (see Baer, 2002).

The opening of archives and the lifting of censorship restrictions, however, have allowed for a more nuanced, evidence-based view of homosexuality in nineteenth and twentieth century Russia.

Homosexuality in Prerevolutionary Russia

It does appear that homosexuality was less rigorously prosecuted in Russia than in the West, at least until the Soviet period. A general attitude of tolerance toward homosexuality appeared to be the norm among the highest echelons of Russian society throughout most of the nineteenth century, as evidenced in Alexander Pushkin's adaptations of ancient Greek and contemporary Arabic poems with homoerotic themes (see Green, 1997) and in Mikhail Lermontov's bawdy Hussar poems. Mikhail Kuzmin's diaries, published only after the fall of the Soviet Union, paint a picture of a thriving gay subculture, and recent research has put an end to the rumors that the composer Petr Chaikovskii committed suicide over a sex scandal with a young boy (Poznansky, 1996). It is now clear that Chaikovskii and his gay contemporaries, including many prominent members of Russia's ruling class, led active and quasi-open gay lives. Nevertheless, Nikolai Gogol's tortured relationship to his homosexuality, which may have led to his early death, as well as the anguished diary entries of Grand Duke Constantine Romanov confessing his extramarital trysts with bathhouse attendants and Chaikovskii's sorrowful letter to his brother about his homosexuality and his decision to marry suggest that there were still powerful religious and social strictures in place against the open practice of homosexuality.

By the end of the nineteenth century, rapid industrialization had moved masses of Russians from the countryside to the cities where they lived beyond the supervision of their families and neighbors; in turn, boarding houses for young, single workers appeared in these cities, and features of a gay subculture began to emerge (see Healey, 2001: pp. 29–49). The Russian *banya* or 'bathhouse' and parks became cruising grounds where the upper and lower classes mingled. Many prominent members of Russian high society, including several Grand Dukes, carried on rather open homosexual liaisons and avoided prosecution. The explorer Nikolai Preobrazhenskii was also a very public figure who led a homosexual lifestyle. The gay and lesbian subculture of the time, as exemplified by the poetry of Aleksei Apukhtin, was characterized by high asceticism and a poetics of euphemism and coded references (Taylor, 2002: p. 12). It was at this time, however, that homosexuality began to enter the public sphere. For example, Vladimir Dmitrievich Nabokov, a prominent public figure in the last years of the empire and father of the writer Vladimir Nabokov, took a public stand against the criminalization of homosexuality on the grounds that the law should not interfere in a person's private life (Engelstein, 1992: pp. 67–70).

In 1905, political and social unrest, expressed in workers' strikes, military mutinies, and peasant protests, swept across the Russian empire. To end the turbulence, a reluctant czar was forced to make concessions that resulted in the Russian Constitution of 1906, which for the first time in Russian history granted Russians freedom of speech and assembly. Restrictive censorship laws were lifted and questions of gender, sex, and sexuality were for the first time in Russian history discussed with relative freedom in the public sphere (see Engelstein, 1992). Homosexuality attained unprecedented visibility in this period. In 1906, the Russian poet and prose writer Mikhail Kuzmin published his novel *Wings*, which recounts the main character Ivan (Vanya) Smurov's symbolic journey toward acceptance of his homosexuality. A success-de-scandale in its time, Kuzmin's novel was only one of many contemporary novels to offer new, frank portrayals of sexual desire. Kuzmin's reputation in Russia, however, is more as a poet than as a prose writer. His poetry, inspired by his homosexual affairs, is marked by a formal sophistication combined with unabashed sensuality, as in the poetic cycle 'The Love of This Summer' (1906), considered by critics to be Kuzmin's artistic credo.

Kuzmin's diaries from 1905 to 1907 reveal a homosexual culture with blurry edges at a time when sexual experimentation was the order of the day. One of Russia's leading Symbolist poets, Viacheslav Ivanov, together with his wife, Lydia Zinovieva-Annibal, hosted a weekly artistic salon in their apartment in a building that came to be known as 'the tower.' Open-minded in matters of sex and sexuality, they were close friends with Kuzmin, who was a habitué of their salon and lived for several years in the same building (Malmsted and Bogomolov, 1999: p. 129). A bisexual, Ivanov produced several poems about his homosexual experiences, which were published in his 1911 book of verse, *Cors Ardens*, under the title 'Eros.' Zinovieva-Annibal made her own contribution to Russian gay literature with her novel *Thirty-Three Freaks* (1907) and her collection of stories *The Tragic Zoo* (1907). But as the titles suggest, these works presented lesbianism in an unflattering light as decadent and perverse. Equally unflattering was the depiction of homosexuality in Fedor Sologub's novel *Petty Demon* (1907), which features a sadistic schoolmaster who sublimates his pederastic urges by whipping the young boys in his charge. The gay writer Riurik Ivniev's collection of poetry *Self-Immolation* (1913) also presents homosexual desire in a perverse, decadent light.

The most sustained treatment of homosexuality in Russia until recently was offered by the writer and philosopher Vasilii Rozanov in a monograph devoted exclusively to homosexuality, entitled *People of the Moonlight* (1911). In this work,

Rozanov exposed and condemned the sexophobia of Russian Orthodox culture. This disgust with sex, Rozanov argues, produced a loss of virility that is embodied in 'spiritual homosexuals.' These are men defined not by their attraction to other men but rather by their lack of attraction to women. While he acknowledges the existence of 'real' homosexuals, most homosexuals he suggests are the products of Russia's sexophobic religious culture. For Rozanov, spiritual homosexuals were a symptom of the decadence of Russian civilization, but the asexuality of Rozanov's homosexuals bore little resemblance to the actual life of gays and lesbians living in Russia at the time, as revealed in the diaries of Konstantin Romanov and Petr Chaikovskii. Two of the most colorful figures of the Silver Age period were Nikolai Kliuev and Zinaida Gippius. Married to the philosopher and writer Dmitrii Merezhkovskii, Gippius was a true gender bender, often dressing as a man and adopting a male persona in some of her lyric poems, perhaps to mask her lesbian desire (Burgin, 1993: p. 85). Gippius' interest in homosexuality was not only personal, but, like that of other members of her milieu, had a philosophical aspect, representing the transcendence of traditional, biologically defined gender identities. As her contemporary Ivanov put it in his diary, "Homosexuality is inseparably connected with humanism" (Malmsted and Bogomolov, 1999: p. 105). Unlike the cosmopolitan Gippius, Kliuev came from the provinces from a family that belonged to the Khlysty sect. Even when he moved to St. Petersburg he continued to dress in peasant garb. Kliuev was one of several 'peasant' poets of the time, but his work was also influenced by the elite Symbolist poets. He was the friend, mentor, and purported lover of Sergei Esenin, who dedicated poems to Kliuev (Chernetsky, 1997: p. 153).

Homosexuality in Soviet Russia

Despite the abovementioned silence of early Soviet law on the subject of homosexuality, the regime never embraced the cause of homosexual liberation, and by the early 1930s, life had become difficult for the gays and lesbians who remained in Soviet Russia. Both Kliuev and Esenin died tragic deaths in the Soviet Union. Esenin committed suicide in 1925, leaving a note written in his own blood. Kliuev was exiled to Siberia where he eventually died. All of Kliuev's unpublished writings, which he had left with an ex-lover Nikolai Arkhipov, were lost when Arkhipov himself was arrested and sent to the gulag (Karlinsky, 1997: p. 151). Kuzmin miraculously avoided prison, dying a natural death in 1936. The members of his circle of intimates, however, did not fare as well. His long-time lover Iurii Yurkun was arrested in 1938 and executed, and the translator Ivan Likhachev, who had been a pall bearer at Kuzmin's funeral, was also arrested and spent many years in the camps, where he translated Baudelaire's *Les fleurs du mal* from memory (Etkind, 1997: pp. 47–48).

Those who were not imprisoned were silenced. The last hurrah of gay-themed literature in Soviet Russia was the miraculous publication in 1929 of Kuzmin's collection *The Trout Breaks the Ice*. This was 1 year after the publication of Konstantin Vaginov's novel *Goat's Song* (1928), which featured the gay character Kostya Rotikov. The lesbian poet Sophia Parnok also found it increasingly difficult to publish her work in the 1920s. Marina Tsvetaeva's poem 'Podruga' (Girlfriend), inspired by her affair with Parnok, was not published until 1979, in the United States. The poet Riurik Ivniev (pseudonym of Mikhail Kovalev), too, ceased publishing homoerotic verse in the Soviet period, and his prerevolutionary poetry was only republished in 1988 (Molnar, 1997: p. 159).

Stalin's consolidation of power in the late 1920s resulted in stricter regulation of what was considered to be 'nonnormative' behavior, and in 1934 homosexuality was criminalized at the same time that abortion was made illegal. But homosexuality had already disappeared from Russian literature by this time. It would also disappear from the Soviet press and as an object of academic study. Kuzmin's final public reading of his poetry in Leningrad in 1928 was perhaps the "last demonstration of Leningrad's homosexuals" (Malmsted and Bogomolov, 1999: p. 349).

While homosexuality disappeared from the public sphere in the Soviet era, the diaries of gays and lesbians who remained in Russia – such as the poets Mikhail Kuzmin and Riurik Ivnev, and the cabaret singer Vadim Kozin – offer an important source of information about the private lives of Russia's sexual minorities. Their diaries document the harassment and everyday humiliations endured by homosexuals at the hands of the regime. (Kuzmin's diary entries of 1905–07 are very different from his entries of 1934.) Many gay, lesbian, and bisexual Russians fled the Soviet Union after the October Revolution and took up residence in various metropolitan centers around the world. Marina Tsvetaeva emigrated to Paris, as did the poet Anatolii Steiger; the poet Valery Pereleshin emigrated first to China, then to Brazil, where he settled. Although the Russian diaspora was only nominally less sexophobic than the Soviet regime, these poets were able to continue working and to find venues in which to publish their work. Pereleshin's magnum opus *Ariel* (1976), which consists of 169 classical sonnets documenting an epistolary romance Pereleshin had with a man in Moscow, was first published in Germany. Gennadii Shmakov, who emigrated to New York City, translated works of gay literature, such as James Baldwin's *Giovanni's Room* and the poems of Constantine Kavafy, while continuing to champion the work of Russia's first openly gay writer, Mikhail Kuzmin, who had been all but forgotten in Soviet Russia.

Homosexuality in Post-Soviet Russia

The breakup of the Soviet Union in the early 1990s was accompanied by the lifting of censorship restrictions, the decriminalization of homosexuality, and the influx of Western NGOs. These changes resulted in new visibility for Russia's sexual minorities and the promise of a lesbian, gay, bisexual, and transgender (LGBT) activist movement. All the trappings of an open gay and lesbian subculture appeared in Russia's largest cities: clubs, magazines, publishing houses, and activist organizations. Moreover, the founding of Russia's first gay Web site, gay.ru, gave provincial gay men and lesbians access to gay-themed books and journals. Although most of these venues were short lived and depended on financial support from the West, they nevertheless made possible the publication of works by new Russian gay and lesbian writers and of translations of Western gay literature, as well as the republication of works by

Soviet and prerevolutionary writers that had been censored by the regime. Some of the most striking events in post-Soviet publishing involved the publication of gay-themed works, such as Kuzmin's frank and witty diaries (1998, 2000) and Kostya Rotikov's gay 'history' of St. Petersburg, *Drugoi Peterburg* (The Other Petersburg, 1997). (Kostya Rotikov is the pseudonym of Iurii Piriutko.) Russia's first anthology of gay literature, *Liubov' bez granits* (Love without Borders, 1997) also appeared at this time; it featured the Russian writers Lermontov, Kuzmin, Zinovieva-Annibal, Ivnev, Esenin, Limonov, and Kharitonov, several of whom were not in fact gay, alongside canonical gay writers of the West, such as Proust and Michelangelo; the cover features a black-and-white reproduction of the Russian artist Aleksandr Ivanov's 1822 painting *Two Models*, portraying two provocatively posed male nudes. These works, which were lauded by some and violently denounced by others, represent early attempts by post-Soviet Russian gays and lesbians to reclaim, or queer, their Russian and Soviet past.

The work of several out gay men – Dmitrii Volchek, Aleksandr Shatalov, Dmitrii Kuzmin, and Iaroslav (Slava) Mogutin – in their work as poets, critics, editors, and publishers has done much to secure the availability of gay- and lesbian-themed literature in today's Russia and to battle long-standing stereotypes that associate homosexuality with asexuality and suffering. However, a deep ambivalence toward homosexuality persists within Russian culture today, reflected in the government's refusal to allow gay pride parades, in new laws to outlaw public discussion of homosexuality, described as 'propaganda,' and in high levels of homophobia. Vitaly Chernetsky describes gays and lesbians as "the most stigmatized and oppressed minority group in contemporary Russia" (2007: p. 146). This ambivalence is also reflected in sensational, often graphic depictions of homosexuality in the mainstream media and in the literary works of non-gay-identified writers designed to shock. In 2001, Elizabeth Wolfe, a reporter for the *Moscow Times*, declared the LGBT activist movement in Russia moribund (10). This is explained not only by opposition from an authoritarian government and an equally authoritarian official church, but by the persistence of Soviet-era sexophobia, manifested in a reluctance on the part of many Russians to discuss issues of sex and sexuality in public, as reflected in new legislation to outlaw 'homosexual propaganda.' All that, combined with the fact that many Russians – straight and gay alike – reject the Western civil rights model predicated on rigid and exclusive identities, makes the future of an open gay and lesbian subculture in Russia uncertain.

Sexual Minorities in South Africa

Zethu Matebeni, University of Cape Town, Rondebosch, Cape Town, South Africa

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Since the demise of apartheid, gay and lesbian people in South Africa have enjoyed equal rights and access to legal reform on many levels. Same-sex partnerships, adoption rights, immigration rights, and other social benefits for same-sex partners have become a norm in South Africa. Though the postapartheid South African constitution grants rights to sexual minorities, the extent of racial and class inequalities within gay politics indicates the need for a revamped movement or politics that will challenge structural injustices and lack of redistribution. Looking at South Africa through the commonly used gay lens is not only limited but also problematic. This lens follows the same forms of exclusion that gay history has revealed. Gender, class, and racial tensions within postapartheid gay politics, as in South Africa as a whole, are easily overlooked when the focus is primarily on freedom and equality.

Historical Roots of Lesbian and Gay Activism in South Africa

Since the 1950s, South Africa has seen an upsurge/interest in gay, lesbian, bisexual, and recently transgender and intersex (LGBTI) issues. Already it must be stated that the priority has been mainly or solely on gay and lesbian issues, with specific attention on white gays and lesbians. Laws and regulations have historically governed sexual and gender minority issues and continue to do so. The Prohibition of Disguises Act 16 of 1969, the Immorality Amendment Act 57 of 1969, the Immorality Amendment Act 2 of 1988, the Alteration of Sex Description and Sex Status, 2003, and others have all been designed to govern genders and sexualities. Alongside there have been social attitudes viewing mainly gays and lesbians as immoral and outcasts. However, while the mode of governing sexual minorities has changed, that is, its legal approach no longer reliant on punishment and exclusion (Cameron, 1995), what remains the same are the stark disparities among sexual minorities themselves.

Cameron (1995: p. 93) argues that the "traditional attitude of intolerance towards gay sexual conduct seems to be deeply ingrained in our legal history." Prior to the end of apartheid, laws governing sexuality prohibited any form of sexual contact between people of the same sex. Such contact was not only outlawed but also regarded as 'unnatural.' Society responded accordingly and stigmatized those involved in such acts branding them as criminals and giving them pariah status. Therefore, we cannot divorce or separate legal struggles from social struggles. These inevitably affect one another. However, what the current South African picture on sexual minorities shows is the disconnect between legal reform and sociopolitical and economic reform with the latter lagging behind the advancement of legal reform. While not difficult to understand why the disparities exist, it is curious that groups who have fought against domination and oppression have remained silent, and most times complicit, on these issues.

The South African Constitution of 1996 is exemplar both for the nation and for the world. It promises and offers rights and freedoms to everyone, regardless of their social category. Accompanying the constitution are significant court judgments and laws that have significantly improved the lives of gay people. A year after the adoption of the constitution, the Cape High Court ruled that the crime of sodomy was unconstitutional. By 1998 sodomy was decriminalized. Many of the subsequent laws, although accessible to all, were a result of legal challenges brought by mostly white gay and lesbian couples. Except for a few, the legal victories focused on economic access or advancement of same-sex couples.

A number of legal victories followed (Judge et al., 2008: pp. 55–57) in 1998 with the court ordering that a lesbian partner could receive benefits from her partner's state medical scheme. In 1999, same-sex life partnerships were allowed to receive the same pension benefits as heterosexual married partners. That same year, the Constitutional Court ruled, "the permanent same-sex life partner of a South African citizen or permanent resident should be granted the same rights as a spouse when it comes to immigration rights." By 2002, same-sex partners could claim equal benefits from the pension funds of their state-employed partners. They could also be joint legal parents of a minor adopted child. A year later, both same-sex partners were allowed to be registered as legal parents of a child born *in vitro* by one partner. The following year a surviving partner of a deceased same-sex person was granted the right to claim damages for loss of support. By 2006, the Constitutional Court confirmed that this would be extended to equal benefits in the case of a partner dying without a will. Within a couple of years, the common-law definition of marriage was declared unconstitutional. This led to the adoption of the Civil Union Act of 2006.

South Africa's Bill of Rights is the world's flagship in the protection and promotion of gay rights. It has made South Africans believe that there are intrinsic commonalities shared by those regarded as 'sexual minorities,' i.e., gays and lesbians. However, in the context of the current postapartheid state, those same groups of people find themselves divided along race, class, gender, and sexuality. Even their commonality as sexual minorities becomes dubious.

A Fractured Movement: The Early Years of Gay Politics in South Africa

From the onset, stark divisions marked the traces of the emergence of a gay and lesbian movement in South Africa.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10245-4

These were on many levels, in relation to politics, race, class, and gender. It appeared quite early on that white gay men would be the major beneficiaries of these divisions. During apartheid, the first signs of a gay movement appeared under the Legal Reform Fund set up in 1966 to oppose antihomosexual legislation in the form of the Immorality Amendment Bill. The fund was established as direct action following a police raid at a famous party in Forest Town, one of Johannesburg's affluent suburbs. Money raised by the fund would go toward legal representation established to investigate the proposed Bill. Although there were a number of lesbians and transsexual people at the party, it has been believed as a gay man's party. Gevisser (1995) calls this the closest equivalent to New York's Stonewall.

Perhaps what likens the subsequent political movements is that both were exclusively white, and both were largely silent about the visibility and role of lesbians, nonwhites, and trans people. This invisibility has remained within what is considered the LGBT movement and activism in South Africa. In reality, transgender and intersex people remain outside the LGBT framework and organize independently. Writing about Stonewall, Christian Williams (2013) states that it has come to be believed that "the middle class white gay men were the real heroes" and thus enjoy the benefits of equality while it was trans people who put their lives at risk. Similarly, the events of the Forest Town raid have been perceived as the resistance of white gay men while trans people and cross dresses who were most visible were arrested for 'masquerading' (Gevisser and Matebeni, 2008).

What was rather curious about the Forest Town party were the events after the arrest of many of Johannesburg's middle and upper class white gays. These events have come to symbolize the fractured state of gay, as well as LGBT politics in South Africa today. The Legal Reform Movement (LRM), set up through the fund, was careful not to align itself with Black antiapartheid movements of the time, as it feared antagonizing the state (Gevisser and Cameron, 1995). These were already indicators of where gay politics of the time would go, toward an apolitical stance unwilling to unsettle government.

In less than 20 years after the raid, the LRM had reinvented itself, only to remain the same. In naming itself, LRM was not explicit and was 'unobtrusive,' although it served the interests of gay people. By 1982 a national organization, Gay Association of South Africa (GASA) was formed, differing from LRM only by name. At this time, it was clear that the agenda for the organization was specifically in the naming of gay (Epprecht, 2012). It soon linked up with the 6010 initiative in Cape Town, as well as with other smaller groups in other parts of the country. GASA, which addressed the psychosocial needs of white gays and lesbians, had an explicit policy of being 'apolitical.'

This was a very crucial time in South Africa as apartheid was at its most volatile and aggressive. Antiapartheid groups were working hard at overthrowing the government. In August 1983, the United Democratic Front (UDF) was launched to resist against apartheid state's increasing repression. While there were gay and lesbian members part of the UDF and other members focusing on a militaristic actions against the apartheid government, GASA, which had formed a year earlier took an apolitical stance. Their mission statement read as follows: "a non-militant, non-political answer to gay needs" (Croucher, 2002: p. 318). So, quite early on, *de facto* white organizations and their constituencies divorced themselves from national politics. Even when GASA's members were in conflict with the state, the organization's stance was to "remain nonaligned in broader South African politics" (Gevisser, 1995: p. 51). So as not to compromise their work by being in conflict with government, GASA refused to speak out against the apartheid state's racist policies. This would later lead to GASA's closure and its exclusion from international gay platforms.

Operating in a tense political climate in South Africa, GASA's mainly white middle-class gay male members were forced to deal with their political conservatism when Simon Nkoli, a black gay man and antiapartheid activist from the township, as well as other black gays and lesbians joined GASA in 1983. Unlike their counterparts in GASA, Nkoli and his followers' sociopolitical conditions were neither uncomplicated nor apolitical. His presence, specifically, was necessarily provocative. He forced GASA to respond to many issues, including the organization's 'apolitical' and segregating stances. Luirink (1998: p. 21) presents a case that GASA was 'apartheid-friendly' in the ways in which it imposed upon its members to change their behavior, 'play it straight, keep a low profile, and to not give offense.' Cock (2003: p. 37) suggests that this ideology was 'patriarchal.'

Emily Craven (2011: p. 30) argues "GASA's supposed policy of remaining apolitical was in fact a very clear political project of accommodation in which there was a decision to negotiate space within the apartheid regime and not oppose it." It was a political stance to benefit white gay interests. Referring to GASA's decision and commitment to voting for the National Party because of its pro-gay attitude, Gevisser (1995: p. 61) argues "far from being apolitical GASA had in fact shown clearly that they would actively support racial repression if it was in the interests of white gay people."

Nkoli, with other members of the UDF, an antiapartheid organization of the 1980s, was arrested after a rent boycott in September 1984. From prison, he sought support from GASA. In 1985, he was charged with treason and was in detention for alleged terrorist activities together with 21 other activists. In response, GASA argued it could not support Nkoli as it claimed that he had played a minimal role in the South African gay movement and because GASA had an 'apolitical' constitution What GASA revealed was its gay political agenda, which was both opportunist (politically) in terms of self-interests and also apolitical (Gevisser, 1995: pp. 48–61). This same framework has taken place also in the fight for equal rights.

In 1988, Nkoli was acquitted and together with mostly black lesbian and gay activists set up the Gay and Lesbian Organisation of the Witwatersrand (GLOW). Unlike previous organizations that had existed, GLOW was overtly political and situated its politics in broader antiapartheid struggles. This was also the time of demonstrations campaigning for democracy and the unbanning of liberation movements. GLOW saw the recognition of human rights as indivisible from other struggles. In actual fact, GLOW's close association with the African National Congress (ANC), South Africa's national liberation movement, sat uncomfortably with many gay people. But as Gevisser (1995: p. 36) notes "even the most anti-ANC of gay

people probably had some sense that their best hope for equality and protection lay with that party." Two years after its formation, GLOW organized the first gay and lesbian pride march in Johannesburg.

Tensions within the South Africa gay rights movement have always existed and have been carried through to the democratic transition. White gays and black gays have been on polar ends. Politically, they have been and remain divided. Due to legal gains, there is an assumption of unity that in reality is a false sense of unity. As Jacklyn Cock (2003: p. 36) poignantly observes "the unity of the gay rights movement should not be overemphasized … the movement was fragmented, splintered politically and divided along race, gender, class and ideological lines."

'Equality for All – Terms and Conditions Apply'

The early 1990s, characterized particularly by black gay and lesbian visibility, saw gay and racial liberation march hand-in-hand. This was exemplified in the first pride march in Johannesburg. At the core of that march, organized by GLOW, was the idea for pride to be a visual symbol for gay and racial liberation. And this was carried out in the speech made by Simon Nkoli at that pride march. Ditsie (2006: p. 19) recounts it as follows:

> I am black and I am gay. I cannot separate the two parts of me into secondary or primary struggles … So when I fight for my freedom I must fight against both oppressions.

It is reasonable to believe that it is at this moment that the already existing tensions and fractures within the lesbian and gay movement solidified. GLOW's successes and ideologies were short lived. By 1994, when the National Coalition for Gay and Lesbian Equality (NCGLE) campaigned for the inclusion of sexual orientation in the new constitution that was being drafted, gay politics had returned to GASA's ideology – not only 'in the interests of white gay people' (Gevisser, 1995: p. 36) but black politics championed by GLOW receded. The NCGLE had orchestrated a community that in actual fact did not exist. Oswin (2007) argues that the coalition, by virtue of being a coalition and thus an umbrella body of between 20 and 75 organizations, managed to create an idea that a community and a unified lesbian and gay movement existed. Gunkel (2010: p. 71) argues that the NCGLE's strategy 'played down differences.' While its success, 'attributed to its single-issue focus' should be applauded, because of this the NCGLE can be likened to the LRM (Cock, 2003: p. 37).

Sexual orientation was included in the equality clause in the Bill of Rights in 1996. Already at that time, there was some dissent. Certain Christian leaders saw the clause as 'undemocratic' (Cock, 2003). For gays and lesbians 'the Constitution created an impression of unity' Craven (2011: p. 32). However, many recognized the existing fractures within the lesbian and gay movement, which would be played out by the infamous 'shopping list,' a litigation strategy that started with decriminalization of sodomy and ended with legal recognition of same-sex marriage (Berger, 2008: p. 18).

Ending with the highly controversial Civil Union Act in 2005, the litigation strategy by the NCGLE (which by then was the Lesbian and Gay Equality Project (LGEP)) to change the law on a number of issues had been considered a white middle-class act. Premiere in the continent and fifth in the world, South Africa allowed gay and lesbian couples to marry or, as many believe, have civil unions or partnerships (Judge et al., 2008). Upon presentation to the public, the Civil Union Bill faced almost outright rejection and opposition. Traditionalists, religious groups and everyone else who were already skeptical of the progressive nature of the constitution and gay rights, argued that same-sex unions would be against the order of nature and African cultural norms (Reid, 2008).

A journalist, John Qwelane, who later became South Africa's ambassador to Uganda (Gerntholtz and Nath, 2010), published a hate speech article lambasting the progressive nature of the constitution and the depreciating morals and values of South African society because of the legalization of same-sex marriage. His article included a cartoon illustration of a man marrying a goat with a headline "when human rights meet animal rights" (Qwelane, 2008: p. 14). The Johannesburg Equality Court later found Qwelane guilty of 'propagated hatred and harm' (News24, 2011).

Although suggested as a poverty-alleviation strategy (Oswin, 2007), the question of same-sex marriage was in actual fact directed at accessing benefits. It was to protect the economic interests of mainly white gay couples. Black gays and lesbians were made to believe that same-sex marriage promoted values of extended familial and community support. It remains unclear how black gays and lesbians have benefited from this law. The LGEP's strategy on marriage, and similarly same-sex marriage, begs to be problematized. It is very odd and worrying that in a country like South Africa, where the state is directly responsible for poverty and gross inequalities, gays and lesbians would seek marriage as a solution to these social ills. The complicit and assimilatory stance that many gays and lesbians have taken toward national politics and the state has made them seem apathetic to wider political struggles.

Oswin (2007: p. 650), following Spivak in Danius and Jonsson (1993), calls the LGEP's stance a "politics of strategic essentialism." She argues that the lobbying efforts deployed to advance constitutional gains have been a "deliberately conservative approach that has been characterized as elitist, unrepresentative, and male dominated" (Danius and Jonsson, 1993). On the one hand, this strategy created a constitution that would protect the rights of lesbians and gay people in South Africa. On the other, it created the category "poor, black gay or lesbian" (Oswin, 2007: p. 666), addressed later.

Perhaps the most interesting period in gay and lesbian politics in South Africa is post 2000. It is at this point that the wild dramatization of 'poor black lesbians and gays' becomes the spectacle that is 'gay' South Africa today. Since the early 2000s two narratives have emerged to symbolize the experiences of gay and lesbian people in South Africa. The one takes shape through the visual display of gay and lesbian pride marches throughout the major towns and cities in the country.

The other, which I deal with later, is the representation of the black lesbian who is the perpetual victim of male sexual violence and murder.

The Politics of Pride

The history of gay and lesbian pride marches goes back to 1991, having started in the streets of downtown Johannesburg with only about 800 people. In just over 20 years almost 20 000 people can be seen taking part in the pride march in the affluent northern suburb of Rosebank. However, the Johannesburg gay and lesbian pride march has simultaneously reinvented itself while remaining a constant reflection of a splintered rainbow nation. This notion of a rainbow nation, while celebrated for displaying the diversity that is South Africa today, is something of an illusion. Gqola (2001) argues that even though symbolic, the rainbow nation hides difference, political struggles, and the sociocultural histories of the South African body politic. The rainbow flag, carried and flown religiously at every gay and lesbian pride march annually, works as a constant reminder of this illusion.

Johannesburg Pride has been the most successful and longest-running pride march/parade in the continent. Over the years, it has claimed various spaces in the city, starting off in downtown Johannesburg and later moving to exclusive suburbs in the northern part of the city. Location of the pride march remains a contestation that marks racial and class differences. The pride march has also afforded different kinds of gay, lesbian, and to some extent transgender people an opportunity to make themselves visible.

At the most recent Johannesburg pride march, a group of black lesbians organized a protest demanding that the pride committee recognize the plight of black lesbians in South Africa. Their request was met by a violent outburst from the white organizers and marchers who demanded that the protesters remove themselves from the 'route' designated for gays and lesbians (SACSIS, 2012). The subsequent events of the clash between white gays and black lesbians have led to the closure of the nonprofit organization that runs Johannesburg pride. As one journalist points out "what transpired (at the Johannesburg Pride in 2012) also served to reveal the deep malady of racism in South Africa" (Schutte, 2012).

For many years, stark racial and class divisions have symbolized Johannesburg Pride that remains a 'fenced off' area in a public park. The fence has similarly marked racial and class boundaries, with black gay and lesbian participants gathering outside the fence in direct protest to the inaccessibility of the commercialized pride venture. In 1 year, a group of pride anarchists stood outside the pride fence in Rosebank wearing T-shirts written "equality for all – terms and conditions apply." A week prior to the pride in Rosebank, many of these same black lesbian and gay people march in the township for Soweto Pride, protesting against hate crimes toward black LGBT people. This is a political march, Soweto Pride, started in 2005 by a Forum for the Empowerment of Women, a black lesbian organization in Johannesburg (Mhlongo, 2008). Only a handful of white gays and lesbians would be seen at this march. These two forms of protest toward what is currently seen as a gay 'parade' have signaled the deep-seated fractures within gay and lesbian politics in South Africa.

As a number of black pride participants have put it, referring to pride parade in Cape Town and Johannesburg:

> … Gay and lesbian people have not been part of eradicating racial domination. Many gay and lesbian people have and continue to be part of the system that maintains the geographical apartheid that is in Cape Town today …. (Ludwig interview, 21 February 2013)

Bringing another form of exclusion that has characterized gay and lesbian politics generally, a trans activist reflects on the ways in which pride marches have ignored trans issues. He argues "transgender people within the LGBT grouping do not find reasons to be proud or even be at the pride marches. The agenda for pride marches has always been about homosexuality. The current challenges related to transgender people accessing identity documents or accessing hormonal therapy have never appeared in the political agendas of pride marches" (Kheswa interview, 21 February 2013).

Current gay politics can no longer continue avoiding structural inequalities and various forms of oppression and racism that exist in South African society. One of the challenges that local gay politics faces in South Africa is the increasing demand for global ideals. It has been argued elsewhere that globalization, capitalism, and commercialization tend to normalize gay and lesbian people for the global market (Gibson-Graham, 2001). When this happens, local politics and resistance shift from a form of 'radicality' to a politics of 'palatability' (Oswin, 2005) that serves the global gay image. This is the one of the issues that has currently faced Johannesburg and Cape Town Pride. An interview with one of the organizers of the antiprotest at Johannesburg illustrates this:

> Johannesburg Pride did not take seriously some of the issues affecting black lesbians in the townships. In particular pride has become a commercial venture benefitting only a few. The politics of resistance and change have taken a back seat, that pride is now just a party, a parade. (Mbandazayo interview, 21 February 2013)

Representation of Black Lesbians in South Africa

The black lesbian occupies a peculiar space in South Africa and the African continent. South Africa is layered with contradictions and complexities. On the one hand, LGBT people form part of the progressive movement and the rainbow nation that is South Africa today. On the other, individual rights to sexual expression, sexual and gender identity are often challenged in the only African state that is praised for protecting diversities. However, there are limits to diversity, at least in the South African context. Those who transgress the boundaries of diversity often get punished in the most gruesome ways. In particular, the existence of minority groups (including women and females) is often under threat. Among South African black lesbian women specifically, one is considered lucky to escape rape, or even murder before their 30th birthday (Matebeni, 2012).

Black lesbian life in South Africa has become synonymous with rape and even death (Schaap and Gim, 2010). The One in

Nine Campaign (2013: p. 1) states "when people in other parts of the world hear about lesbians in South Africa through the media, almost the only thing they are likely to learn is that butch, black, soccer-playing, lesbians in townships are raped, and sometimes killed, by black men who wish to 'correct' them …." Another media report reads, "Being a lesbian in South Africa can be a death sentence" (Turley, 2012). This is the popular representation of black lesbians in South Africa today, both in public discourse and in academic texts.

Black lesbian life has always been portrayed not only as undesirable, but also through the narrative of victimhood, and to a lesser extent, criminality. In this narrative, the black lesbian remains the object that is made to disappear, in various ways. This is seen in the first appearance of a queer female figure, Gertrude 'Gertie' Williams, in a story published in Drum magazine in 1956 and later reprinted in Gevisser and Cameron's Defiant Desire (1995). In this article and ones that followed, Gertie was termed a 'lesbian gangster' and was imprisoned (Chetty, 1995: p. 128). She was a referred to as a criminal – a female figure who could not be seen as a woman. Lisa Downing's (2013) current body of work on female murderers and criminals suggests that in areas like crime women are treated with an unquestioned prejudice. For example, she quotes Jeffner Allens' assertion that can remain unproblematized in the study of female criminality, "a woman is not violent and if violent, a female is not a woman" (Lisa Downing, 2013: p. 165).

In similar vein, a more contemporary look at black South African lesbians shows that they are easily publicly humiliated and punished for being a lesbian. It was in the public eye when Zoliswa Nkonyane, a 19-year-old lesbian, and her friend were approached while walking home by some girls in their township who claimed that the two 'wanted to be raped' because they were 'tomboys' and living as out lesbians. In the altercation, Zoliswa was clubbed, kicked, and beaten to death by a group of men in full view of people walking by (Thamm, 2006). This kind of public violence works in ways that communicate to black lesbians and noncomforming females that their sexuality and gender can 'be done away with' publicly, in the presence of witnesses. In addition, this is a way in which men control not only women's bodies, but also maintain patriarchal spaces. Many other women have been similarly done away with in such violent ways. (Sizakele Sigasa and Salome Masoa, a black lesbian couple raped and murdered in 2007 in Johannesburg; Thokozane Qwabe, a 23-year-old black lesbian raped and murdered in 2007, in KwaZulu-Natal; Sibongile, a black lesbian raped and murdered in 2008 in Cape Town; Eudy Simelane, a black lesbian murdered and suffered attempted rape in 2008 in Johannesburg; Khanyiswa, a black lesbian murdered in 2008 in Port Elizabeth; Ncumisa Mzamela, a 21-year-old black lesbian burnt to death in KwaZulu-Natal in 2010; and the following (with age): Nokuthula Radebe (20), Ntsiki Tyatyeka (21), Khanyiswa Hani (25), Tshuku Ncobo (26), Mpho Setshedi (27), Sanna Supa (28), Hendrietta Thapelo Morifi (29), Phumeza Nkolonzi (18). There are many others whose victimization, rape, and murder remains unreported and undocumented (source www.iranti-org.co.za).)

The heightened and special focus on violence toward black lesbians, in the context of wider forms of violence toward women and gender nonconforming persons in South Africa, has warranted some critique (Hames, 2011; Matebeni, 2013; One in Nine Campaign, 2013). In this narrative, the black lesbian is made to become the victim of a specific and directed form of violence easily deemed 'corrective' or even 'curative.' The concept 'curative/corrective' rape, now used widely by the media and other publics (Muholi, 2004), defines 'curative' rape, as the "rape of women perceived of as lesbian by men as an ostensible 'cure' for their (aberrant) sexualities" (Muthien, 2007: p. 323). Without any form of interrogation, the world as South Africans themselves have stripped the black lesbian of any other existence but the sight of a victim of 'corrective rape,' and eventually murder (Kelly, 2009).

This form of violence toward nonconforming women should not be seen as 'special' or even isolated. Currently, what is regarded as against the 'norm' is seen as worthy of punishment. People, whose sexuality is seen as nonnormative, although not articulated in this language, often fall victims to violent acts or prejudice. Previous cases such as those of women murdered in some townships in South Africa because of their HIV status are exemplary of such violence and prejudice. (Lorna Mlosana, 21 years of age, was raped in a toilet outside a shebeen/tavern in 2003 in Khayelitsha Township, Cape Town. After raping her, her attacker then beat her to death in a fury when she told him she was HIV positive (www.tlac.org.za, 2006). In a similar case, Gugu Dlamini, 36 years of age, from KwaMashu Township outside Durban was murdered in 1998 after she courageously publicly disclosed her HIV status on World AIDS Day. She was accused of shaming her community and suffered repeated threats and assaults that lead to her fatality (www.Beatit.co.za, 1998). The violent attacks and the murders of women disclosing their HIV status are perpetuated by the 'misogynistic notion that women are the primary vector of the HIV virus and thus deserving of death' (Salo and Gqola, 2006: p. 4).

The victim narrative of black lesbians is a problematic limited view of how black lesbians and gender nonconforming female persons experience the fullness of their lives. Rape and forms of sexual torture perpetrated on women's bodies are problematic, not only with regards to what they do to the victims and society. The language in which they are constructed and communicated veils the violent essence of the actual violence.

Gibson-Graham (2001: p. 241) suggest that there are different ways in which the victim narrative or victim role, which is "prescribed by the rape script," can be challenged. The most obvious way would be a refusal to "accept the victim role" (pp. 245, 248). A number of strategies can be put to use to do that, including 'using speech in unexpected ways, diminishing the power of the perpetrator, and rescripting the effects of the rape on the victim.' In particular, they suggest that a change in the representation of rape – to see rape as 'death, an event that is final and lasting in terms of the damage it does to self' (Gibson-Graham, 2001). Black lesbian groups challenge patriarchy and violence in South Africa by deploying various strategies, including legal representations in court as well as advocating for legislations against hate-related crimes.

Sexual Minorities in South Africa Today

The vision for the South African legal framework for sexual minorities has focused on conformity. As De Vos and Barnard (2007: p. 825) point out "considering the structural divisions of our apartheid legacy, it was specifically important from an integrative point of view that same-sex and heterosexual couples be brought together under one common institution … And this form of integration is indispensable as part of the normalization of post-apartheid South African society as a whole in the conformity with the constitutional ideal of openness." This vision, while important and significant in moving sexual minorities forward, has presented a number of challenges. The situation for black and lower class sexual minorities does not reflect the dream and pursuit of freedom for which many have fought. Racial, class, gender, and political tensions have brought many divides within the gay body politic, many of which cannot be easily solidified. It will take gay and lesbian people to rise up and take note of the divisions existing among them. Only through such political consciousness can South Africa become a better place for all.

Sexual Minorities in the Maghreb

Jarrod Hayes, University of Michigan, Ann Arbor, MI, USA

Abstract

Maghrebian culture going as far back as the classical age of Arabic literature is rich with representations of sexual minorities, and a number of studies in the social sciences examine its importance in Maghrebian societies, even though the latter are often lacking in case studies or field work. Since the 1950s, literature and films in French and Arabic have seen a renewed interest in sexual diversity. And like the several studies on sexuality in the social sciences written since the 1970s, contemporary cultural production has often rewritten the history of sexuality to understand the present. In short, literary and other cultural texts can also be of interest to social and behavioral scientists interested in the Maghreb.

Background

The Maghreb (or predominantly Muslim and Arabo-Berber region of Northwest Africa) has an extensive archive acknowledging sexual diversity. For example, the thirteenth-century *Delight of Hearts*, by 'Tunisian'-born Ahmad al-Tifashi, catalogs the amorous activities of *eunuques*, transgendered folk, go-betweens, prostitutes, libertines of all sexes, adulterers, pederasts, kept boys and women, and *epheboi*. It describes such 'sexual' acts as slapping, genital massage (or rubbing, especially among women), and sodomizing men while they sleep without waking them up. What stands out about its methodology are its generous quotations of literary texts, the most notable of which are the poems of Abu Nuwas, the eighth-/ninth-century Arab-Persian poet known for his praise of wine and the love of boys and women.

Texts such as this have often been deployed by partisans of both sides of the essentialism/social construction debate regarding the history of homosexuality. In the early days of the gay liberation movement, as historians sought evidence for the historic roots of Western lesbian and gay identities, writers such as Marc Daniel saw in classical Arabic literature evidence of gay men throughout history. Gay Sunshine, the same press that included Daniel's study in the collection *Gay Roots*, would only partially translate the French translation of al-Tifashi, offering the 'gay' parts, thereby imposing a hetero-/homosexual binary that is absent in the text as a whole. Likewise, John Boswell, in his foundational study for lesbian and gay studies, would write in 1980:

> Although the Qur'an and early religious writings of Islam display mildly negative attitudes toward homosexuality, Islamic society has generally ignored these deprecations, and most Muslim cultures have treated homosexuality with indifference, if not admiration. Almost without exception, the classical works of Arabic poetry and prose, from Abu Nuwas to the *Thousand and One Nights*, treat gay people and their sexuality with respect or casual acceptance. (pp. 194–195)

From the other side of the essentialism/social construction debate, in the foundational first volume of his *History of Sexuality*, Michel Foucault would reinforce the social constructionist argument when he defined the *scientia sexualis* that characterized Modern Western societies against "the societies – and they are numerous: China, Japan, India, Rome, the Arabo-Moslem societies – which endowed themselves with an *ars erotica*" (p. 57). Along the same lines, Arno Schmitt would write, "But in these societies there are no 'homosexuals' – there is no word for 'homosexuality' – the concept is completely unfamiliar. There are no heterosexuals either" (Schmitt and Sofer: p. 5).

Western (Mis)understandings of Sexuality in the Maghreb

Orientalism

Although deployed in the essentialism/social construction debates, discussions of sexuality in the Arab world have too often been based on a questionable understanding of same-sex eroticism and desire among Muslims. For example, in spite of its constructionist stance, *Sexuality and Eroticism among Males in Moslem Societies*, the 1992 collection that Schmitt edited with Jehoeda Sofer, nonetheless produced a culturally essentialist vision of an absolute Muslim difference when it comes to sexuality, a vision saturated with colonial prejudices and Orientalist stereotypes, including the counting of experiences of sexual tourism as anthropological or sociological evidence.

In his foundational work on Orientalism, Edward W. Said (1978) highlighted the sexual aspects of European understandings of the 'Orient,' itself a colonial invention. Connecting the sexual and epistemological connotations of the word 'penetration,' Orientalist penetration (understanding and knowledge) and its parallel in colonial penetration (military invasion) both come to have sexual implications: "The Middle East is resistant, as any virgin would be, but the male scholar wins the prize by bursting open, penetrating through the Gordian knot despite 'the taxing task'" (p. 309). These implications take on a very literal component in representations of European travelers' sexual experiences in the 'Orient,' because "the Orient was a place where one could look for sexual experience unobtainable in Europe" (p. 190). Furthermore, some of these experiences would have been considered nonnormative from a Western perspective. So when Said writes, "The Orient becomes a living tableau of queerness" (p. 103), although 'queer' did not yet have the implications it does today, this citation may indeed now be read in its contemporary meaning.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10256-9

In *Desiring Arabs* (2007), Joseph A. Massad characterizes Schmitt and Sofer's representation of Arab and Muslim desires as Orientalist just as he does with Boswell's (164–169). To this list he also adds Stephen O. Murray and Will Roscoe's 1997 *Islamic Homosexualities: Culture, History, and Literature* (Massad: pp. 170–171). Furthermore, in Massad's view, Orientalism continues to have an enduring influence in not only Western but also Middle Eastern and North African writings on sexuality in the Arab world. He criticizes, for example, Moroccan feminist Fatima Mernissi, who according to him, "in classical Orientalist manner, employed seventh- through sixteenth-century Arabic texts to *interpret* and *explain* not medieval but *modern* Arab society" (pp. 154–155). In this critique, he also mentions Fatna Aït Sabbah's *La femme dans l'inconscient musulman: Désir et pouvoir* (1982) (*Woman in the Muslim Unconscious*), whom he suggests is like Mernissi (in fact, the website of the Sorbonne's Institut européen en sciences des religions states that Aït Sabbah is a 'nom de plume' for Mernissi), and he argues that the latter's work is intended for a Western audience. In an analysis of Qur'anic, juridical, erotic, and courtly literature, Aït Sabbah examines representations of women's sexuality and devotes almost half the book to the archetype of the 'omnisexual woman.' This figure reduces woman to her vagina, which is characterized by the ability to suck in all it comes in contact with. The omnisexual woman, who desires giant penises as well as sex with women, can never be satisfied sexually. While this is a set of stereotypes that predominantly apply to women, there are omnisexual men as well.

Massad's list of Orientalist writing on sexuality by Arab writers also includes Tunisian social psychologist Abdelwahab Bouhdiba's 1975 *La sexualité en Islam* (*Sexuality in Islam*). Like Aït Sabbah, Bouhdiba does not focus specifically on the Maghreb but on Muslim societies in general. His work offers a psychological survey of the Qur'an, Islamic law, and classical Arabic literature, especially that of an erotic nature, the first and foremost of which is *Alf layla wa layla* (*A Thousand and One Nights* or *The Arabian Nights*). Bouhdiba's word of choice for same-sex desire is homophilia, and his discussion of it is not ghettoized in a single chapter of the book but is mixed in throughout with discussions of the division between the sexes, marriage, the meaning of body hair, the place of sexuality in heaven, the *hammam* or public bath, the practice of circumcision, veiling, as well as illicit sexual behaviors (which include ones committed between members of the same sex): sodomy, pederasty, cross-dressing, prostitution, and both puritan and obscene folklore. To his citations of classical literature, Bouhdiba adds references to contemporary literature in both Arabic and French. Examples of the latter include the Algerian Rachid Boudjedra's 1969 novel *La repudiation* (*The Repudiation*), which will be discussed again below.

Though not considered by Massad, Algerian anthropologist and psychoanalyst Malek Chebel's *L'esprit de sérail: Perversions et marginalités sexuelles au Maghreb* (1988) (*The Seraglio Spirit: Perversions and Marginal Sexualities in the Maghreb*), in its very title, deploys a stereotypical image from Orientalist discourse (a gesture Massad would no doubt criticize). (The seraglio is an Orientalist reference to the harem – women's portion of the house into which nonrelative males are not admitted – and it often tends to imply inclusion of a large number of female slaves and concubines in addition to wives.) Chebel's work contains seven chapters, one on each of the following topics: (1) homosexuals, perverts, and androgynes; (2) obscene language; (3) the virginity taboo; (4) sexuality and the veil; (5) erotic literature in Arabic; (6) ululations; and (7) circumcision.

Ahistoricism

As in Massad's critique of Mernissi quoted above, a key aspect of Orientalist characterizations of sexuality in the Maghreb involves using the past to explain the present in a way that conflates the two. Since the publication of Johannes Fabian's *Time and the Other: How Anthropology Makes Its Object* (1983), cultural historians and social scientists have been more reluctant to compare non-Western societies and cultures to periods from the Western past. Yet while one might think that such Western ahistorical readings of classical texts could be responsible for such homogenizing accounts of any so-called Arab or Muslim sexuality, a small but significant body of studies of sexuality by Francophone Maghrebians has continued the process of generalizing across vast historical periods by similarly citing historically vast bodies of Arabic (and, increasingly, French) texts to offer accounts of sexuality with similar claims to comprehensiveness. Aït Sabbah, Bouhdiba, and Chebel already discussed above all fall into this category.

Homogenization

Ahistoricism itself might be considered but one part of a more general homogenizing approach to sexualities in the Muslim world or in North Africa and the Middle East as an all-inclusive region. Murray and Roscoe's *Islamic Homosexualities* would likewise survey historical periods from the pre-Islamic era to the present in a much more anti-Eurocentric approach that was also less concerned with a binary opposition between the Islamic world and the West. Nonetheless, their title does reveal a certain bias in that it characterizes the Muslim world as homogeneous to a much greater extent than what obtains in Western scholars' treatment of their own societies. Who, for example, in the West would think of entitling a comparable study on the West 'Christian Homosexualities'?

The Maghreb Writes Back

Social Sciences

While Massad's critique of an Orientalist assertion of a timeless essence regarding Arab sexualities must certainly be acknowledged and valued, there is an alternative way of understanding Bouhdiba's and, especially, Aït Sabbah's and Mernissi's readings of classical texts. This alternative would understand their interpretations as precisely that, rereadings of the past that strategically seek to make interventions in the present. In a Maghrebian context, especially in the periods prior to, during, and after the civil war in Algeria in the 1990s, a number of writers have looked to the past to challenge an Islamist monopoly on Islamic 'tradition' and religious writings as well as to assert a more heterogeneous version of the past as a way of effecting change in the present. Indeed, this is the stated goal of many of Mernissi's writings.

In contrast, one might argue that the same is the goal of more recent Maghrebian writings on sexuality; two in particular also happen to have restricted their assertions to the Maghreb (in the first case, Chebel) and even more specifically Morocco (in the second, Serhane). For example, one might argue that Chebel recuperates the Orientalist cliché of the seraglio in the interest of promoting tolerance for sexual diversity. While the first edition of this work was published before the Algerian civil war was in full swing, its reissue in the midst of that war in 1995 was under a significantly less titillating title: *L'esprit de sérail: Mythes et pratiques sexuelles au Maghreb* (*The Seraglio Spirit: Sexual Practices and Myths in the Maghreb*). One must therefore wonder whether this change in title was meant to make the work more palatable to a wider readership.

While many have focused on Massad's critique of a 'gay international' that attempts to impose Western constructions of sexuality onto the Arab or Muslim world, Chebel might also be associated with the secularist Arabic-language scholars examined by Massad, those who have explored the applicability of the concept of sexuality to the Arab world. In spite of the prominence Chebel gives to 'homosexuality' by discussing it in his first chapter, like Bouhdiba, Chebel contextualizes same-sex desire within a variety of other sexual practices with the effect of normalizing the 'perverse' or, conversely, of demonstrating how central 'perversions' are to Maghrebian sexual and gendered practices. This is what in the West would be called queering as a critical and theoretical practice, one that also involves a certain work of translation, between Arabic and French, between European and Arab or Muslim cultures, between the premodern and the modern. Indeed, many of the contemporary Arabic-language writers whom Massad discusses also consider the long tradition of Arabic 'sexology.'

Massad's extensive work on 'translations' (like those mentioned above) from French or Anglophone works and concepts into Arabic constitutes a much more complex account than what many of his critiques have allowed for. And as Sahar Amer demonstrates (2008), such translation has not always been a one-way street, but has instead 'gone both ways.' Furthermore, Chebel goes further than Bouhdiba in his use of contemporary French-language writers such as Boudjedra, Mohammed Dib, Kateb Yacine, Aicha Lemsine, and Abdelhak Serhane, some of whom will be discussed again below. Chebel has also, by now, produced a considerable body of additional works related to sexuality or eroticism in the Maghreb: *Le corps dans la tradition au Maghreb* (1984) (*The Body in Maghrebian Tradition*), *La féminisation du monde: Essai sur "Les Mille et Une Nuits"* (1996) (The Feminization of the World: Essay on the "Thousand and One Nights"), *Histoire de la circoncision: Des origines à nos jours* (1992) (*The History of Circumcision from Its Origins to the Present*), *Le livre des séductions* (1986) (*The Book of Seductions*), and *L'encyclopédie de l'amour en Islam: Erotisme, beauté et sexualité dans le monde arabe, en Perse et en Turquie* (1995) (*The Encyclopedia of Love in Islam: Eroticism, Beauty, and Sexuality in the Arab World, Persia, and Turkey*). *La féminisation du monde* is especially notable for its treatment of 'homosexuality,' including Chebel's most extensive discussion of lesbianism.

Furthermore, in contrast with the geocultural generalizations of Mernissi and Bouhdiba, over time the social science on sexuality has increasingly circumscribed its purview. The second of the more recent Maghrebian works on sexuality is psychologist Abdelhak Serhane's 1995 *L'amour circoncis* (*Circumcized* Love). (Serhane is most known, however, as a novelist.) As mentioned above, this work, the most recent in a series of Maghrebian studies on sexuality, is also the most circumscribed geoculturally, restricting as it does its purview to the sole country of Morocco, even though, thematically it overlaps a great deal with its more general predecessors. After a first part on the socialization or typical development of the Moroccan child and a second one on the role of women, the place of sexuality in Moroccan tradition, and father- and motherhood, part three treats such topics as circumcision, masturbation, homosexuality, bestiality, the *hammam*, prostitution, and marriage. Again, by placing the institution of marriage at the end of a longer list including nonnormative practices, Serhane echoes Chebel's tactic of 'queering' the normative and normalizing the 'queer.' Serhane also stands out in his emphasis on more contemporary sources, including Mernissi (and with her the field of sociology) as well as Freud (and with him psychoanalysis), the latter of whom Serhane characterizes as antifeminist. Furthermore, Serhane supports his discussion of contemporary Moroccan society with quotations from the Qur'an and other religious texts as well as from classical literature, along similar lines as the writers discussed above.

In spite of its more specific context, then, *L'amour circoncis* covers similar ground as Bouhdiba and Chebel, both of whom Serhane cites. Yet more than Bouhdiba and Chebel, in many of his points Serhane reads like barely veiled allusions to contemporary Maghrebian literary production in French. One example is his description of same-sex sexual abuse in Qur'anic schools, of which an episode is described in Boudjedra's *La répudiation*. Another would be Serhane's considerable discussion of zoophilia, also described in a page-long comparison in Rachid Mimouni's *Le fleuve détourné* (1982) (*The Diverted River*) of the advantages and disadvantages of sex with a goat, cow, and she-ass, the last of which wins this particular 'contest' (pp. 39–40). In fact, in many ways, *L'amour circoncis* reads like an essay version of representations of sexuality in Serhane's novel *Les enfants des rues étroites* (1986) (*Backstreet Boys*), which itself might also remind readers of *La répudiation*. The latter contains the most extensive, detailed, and explicit representation of two boys having sex in view of the entire family of one of them. In his 1983 *Messaouda* (pp. 133–134), Serhane mentions 'nouiba,' which entails boys' taking turns sodomizing one another. The eponymous character of this novel is an androgynous prostitute, initiator of boys, and witch.

Literature

1950s

Well before the 1980s, which saw the publication of Serhane's first novels, the foundational 1950s generation of Maghrebian writers began to distinguish their literary production in French from that of metropolitan France often in the form of colonial childhood narratives. These novels were the first to assert a certain sexual diversity, especially among boys and unmarried men. The first edition of Mouloud Feraoun's *Le fils du pauvre* (1950) (*The Poor Man's Son*) mentions sex between boy

cousins. In Mouloud Mammeri's *La colline oubliée* (1952) (*The Forgotten Hill*), the narrator's cousin has a homoerotic relationship with a musician/dancer. Albert Memmi's *La statue de sel* (1953) (*Pillar of Salt*) describes collective sex play among teenage boys of mixed ethnicities. Formerly the passive partner in anal intercourse, the male protagonist of Driss Chraïbi's *Le passé simple* (1954) (*The Simple Past*) insists on being the active partner with other men as he reaches adulthood.

1960–90

Since the 1950s, representations of sexual diversity have not abated; indeed they have become more frequent. In fact, rare is the Maghrebian writer who has not incorporated representations of male same-sex desire in at least one novel. Others, like Boudjedra and Tahar Ben Jelloun include it in several works. Representations of female same-sex desire are rarer, but far from nonexistent. In the French version of Boudjedra's *La pluie* (1987) (*Rain*), the narrator has a lesbian aunt. The female transgender protagonist of Ben Jelloun's *L'enfant de sable* (1985) (*The Sand Child*) has a sexual encounter with (another) woman after his or her wife dies. As part of her life story, the female narrator of *Les yeux baissés* (1991) (*Downcast Eyes*) describes a homoerotic encounter with another girl that leads to a more sexual dream. Merzak Allouache's novel *Bab el-Oued* (1995) includes an affair between two women (though it is not included in the film version). In less explicit terms, Assia Djebar stages a number of homoerotic encounters within the women's *hammam* in *Ombre sultane* (1987) (*A Sister to Scheherazade*) and in the title story of *Femmes d'Alger dans leur appartement* (1980) (*Women of Algiers in Their Apartment*)

In "Défendre la diversité culturelle au Maghreb" (1991) (Defend Cultural Diversity in the Maghreb), Ben Jelloun also defends representations of sexual diversity and claims that Maghrebian novels in French have been at the forefront of challenging the status quo through sexual transgressions. Yet he himself translated one of the most important contemporary Arabic texts in this regard: Mohamed Choukri's *Le pain nu* (1980), translated into English as *For Bread Alone* (1973), is an autobiographical narrative of growing up in poverty amidst petty crime, drugs, and prostitution, and although most of the prostitution is heterosexual, the male narrator recounts one episode of selling sex to an older man. Since 1982, Boudjedra has written his novels in Arabic first. While there are differences between the Arabic 'originals' and their French 'translations,' same-sex desire is far from absent from the Arabic versions.

1990–Present

After a rich tradition of supposedly heterosexual representations of queer sexualities, a handful of openly homosexual writers began to publish in the 1990s. Beginning in 1995 with *L'enfant ébloui* (*The Dazzled Child*), the Moroccan Rachid O. has written four autobiographical novels in which he relates his cross-generational loves as a boy and his affairs with European men as a young man. In *Un "poisson" sur la balançoire* (1997) (*'Fish' on the Swing*) and its sequel *Une promesse de douleur et de sang* (1998) (*A Promise of Suffering and Blood*), which are explicit enough to be characterized as erotica, Eyet-Chékib Djaziri recounts the boyhood loves and affairs of a binational, French-Tunisian protagonist. The Moroccan Abdellah Taïa has also written a number of autobiographical novels in which the main character's desire for other boys (as a younger boy) and men (as he grows up) plays a prominent role. From novel to novel, he describes same-sex relations in both Morocco and Europe. In *L'armée du salut* (2006) (*Salvation Army*), the narrator explicitly describes his sexual desire for his beloved brother Abdelkébir (the same family names recur from novel to novel)

Although she might deny the label lesbian writer (as she denies those of woman, French, or Algerian writer), Nina Bouraoui sets a lesbian love story in a Swiss girl's boarding school in *La vie heureuse* (2002) (*Happy Life*). In her previous *Garçon manqué* (2000) (*Tomboy*), a female narrator refuses to accept being assigned a gender. Finally, any discussion of Maghrebian gay writing in French must also include Jean Sénac, an Algerian poet of European origins. In spite of openly praising the love of boys, he was a member of the Ben Bella government after independence and, even after being marginalized by Boumédiène's coup in 1965, went on to host a radio show on poetry that rivaled the popularity of television.

Film

There have also been a number of films treating aspects of same-sex desire in the Maghreb. *Rih essed* (*Man of Ashes*) (1986) tells the story of a groom-to-be who remembers being sexually molested as a boy apprentice by his master. By the same director, *Bezness* (1991), whose title is the Tunisian word for 'beach gigolo,' tells the stories of male prostitutes with both men and women clients in Tunisia on vacation. Referred to by some as the 'Algerian Almodovar,' Nadir Moknèche directed one film, *Viva Laldjérie* (*Viva Algeria*) (2004) that contains scenes of public sex between men. *Le fil* (*The String*) (2009) is about a France-based architect who returns to Tunisia and falls in love with his mother's gardener, a monolingual Francophone son of Tunisian parents who has reverse migrated (back) to Tunisia. The architect also enters into an arranged marriage with a lesbian friend so that the son of her and her partner can have a legally recognized father.

Conclusion

In short, Maghrebian culture is rich with representations of sexual minorities, and a number of studies in the social sciences examine its importance in Maghrebian societies, even though the latter are often weak in case studies or field work. In the 1996 gay-pride issue of the Parisian daily *Le monde*, however, a writer going by the name of Anis described an aborted attempt to organize a lesbian and gay movement in Algeria during a brief window of political opening at the end of the 1980s. Placed in a history with Sénac, this historical detail could only suggest what political possibilities lay ahead.

Sexual Minority Families of Choice and Family Networks: We Are Family

Emily E Wheeler and Sharon G Horne, University of Massachusetts Boston, Boston, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

In the lesbian, gay, bisexual, transgender, and queer (LGBTQ) community, the concept of 'family' has different meanings. Historically the right to form a traditional family (e.g., two parents and children) with associated legal rights and protections has not been an option for LGBTQ couples. In the absence of formal family arrangements, LGBTQ individuals have created their own family and community structures. Yet, over time, steps have been taken to create and legitimize family rights for LGBTQ people, and as social and political attitudes and norms have changed and laws and policies followed suit, so has the ability of LGBTQ individuals to form legally recognized family structures.

Family of Choice

Family and kinship have long been associated with groups bonded via marriage and birth. The prototypical nuclear family and its companion, the extended family, have been firmly entrenched in the modern history of the American family. It is in the context of this history, as well as the limits placed on lesbian, gay, bisexual, transgender, and queer (LGBTQ) couples by heterosexism and anti-LGBT violence, laws, and policies found throughout the United States, that Kath Weston's (1991) ethnographic study of lesbian and gay individuals living in and around the San Francisco Bay area, *Families We Choose*, challenged this definition within that community.

Weston's (1991) work elicited several important insights about how the 80 men and women she interviewed (in addition to herself, as a reflective participant) conceived of kinship. Her account captured a more fluid conceptualization of family, and one that was not necessarily predicated on marriage and 'blood' relationships. Weston's participants shared a range of responses to their disclosure of their sexual identities to their 'straight families,' 'families of origin,' or 'biological families,' some of which had been maintained through the process of revealing their sexual identity and some of which had not. However, most remarkable about this work was the experience participants shared of their 'gay families,' the titular 'families we choose,' or 'families of choice,' which they defined as the networks of current and former romantic partners and friends.

What was perhaps most provocative and important about Weston's (1991) account was that her intimate descriptions of these family of choice bonds challenged the idea that the strength of family ties is predicated on those of the more traditional nuclear family structure. At the time of its publication, marriage was long from being a legal possibility for same-sex couples in the United States and many states prohibited adoption by second-parents of the same gender. Thus, legally prohibited from traditional 'family' structures and at times having been rejected by families of origin, Weston described the means by which her participants negotiated life through kinship ties to their gay families, including culture and identity building.

These two kinds of family structures (family or origin and family of choice) are not meant to be mutually exclusive, nor are families of choice a replacement for families of origin. Indeed, families of choice may include chosen family of origin members. Family bonds are meant to be characterized by strength and durability, beyond a collection of one's close friends or relations. Families of choice were a means of accessing a particular kind of support around sexual identity and related issues that could not be assumed in other relationships.

Gay and lesbian communities and neighborhoods have also been viewed as part of an extension of family of choice. Levine's (1979) landmark essay 'Gay Ghetto' was the first to describe the phenomenon of urban physical spaces occupied by a community of gay individuals in sociological terms. The term 'ghetto' was meant to elicit comparison to other cultural communities that had been segregated, and gay ghettos, also known as 'gay enclaves,' have most often been associated with the gay male community, albeit not exclusively. Salient examples include the Castro district in San Francisco, Christopher Street in New York, Key West in Florida, and Provincetown and Northampton, Massachusetts. These neighborhoods have served as spaces that allow a freedom of expression not otherwise possible and have also been homes for LGBTQ-based organizations and institutions. Further, and not unlike families of choice, these communities have often served as a means of culture shaping and maintenance by acting as sites of communication and storytelling, as well as collective action (Usher and Morrison, 2010).

LGBTQ Families in the Twenty-First Century

As the legal, political, and social landscape has shifted for the LGBTQ community, so too has the concept of family. Yet families of choice, as Weston (1991) described them, have continued to be important for many LGBTQ individuals. The family of choice concept has found some empirical support; LGB individuals maintain more friends as confidantes as they age than the general population, whereas the general population maintains connection with more family of origin members (Dewaele et al., 2011). Oswald (2002) applied the family resilience model to gay and lesbian families and described two main processes that characterize these networks: intentionality and redefinition. Intentionality refers to the

processes by which gay and lesbian individuals create networks in a nonaffirming environment and includes acts such as choosing family members, creating rituals, and building a sense of community. Redefinition refers to processes by which gay and lesbian people and their family networks are affirmed, and includes such acts as acknowledging the role of heterosexism in their experience and giving family members named identities. Such an approach to family uses the concept of resilience to highlight the ways in which these family networks are a means of coping with the risks and challenges that result from stigma and oppression.

The role of families of choice have also been explored among more specific groups such as aging lesbian women (Ariel, 2008); rural gay men (Cody and Welch, 1997); gay men with HIV (Nord, 1996); African-American men who have sex with men (Kubicek et al., 2012); and gay, lesbian, and bisexual youth (Nesmith et al., 1999). These kinship networks have been described in the literature as a critical source of support for LGBTQ individuals, both for issues and stressors related to sexuality and gender identity.

Many LGBTQ men of color participate in created families that are known as gay families or 'houses.' These social networks can include members who participate as 'parents' or 'grandparents' and mentor and support 'children' who are often younger men who have been rejected by families of origin or who experience sexual stigma in their ethnic communities and racial stigma in majority culture (Phillips et al., 2011). These families are often connected with dance or modeling performances in 'balls' and these networks typically embrace a range of gender expressions and identities. Houses have been found to be important for HIV prevention and intervention efforts within communities of color by helping men to reduce risky sexual behavior (Arnold and Bailey, 2009).

The support of other LGBTQ individuals is of particular importance in an environment in which heterosexism continues to proliferate and experiences of discrimination and harassment on the basis of sexuality and/or gender are all too common (Almeida et al., 2009; Hequembourg and Brallier, 2009; Nadal et al., 2012). Families of choice create alternative environments in which individuals can experience safety and where they can communicate honestly about their sexuality and gender. Much like the way traditional family structures are conceptualized, family of choice relationships offers a stable source of support over time as well.

While family networks have persisted within the LGBTQ community, traditional 'gay enclaves' have experienced more change. In a *New York Times* article, Brown (2007) questioned if such neighborhoods were 'passé' due to the sometime marked changes over the last several decades. In their chapter, Usher and Morrison (2010) described that these areas have experienced a demographic shift as more heterosexual individuals have moved in and LGBTQ residents are more often married and have children or have moved into outer urban neighborhoods and suburbs. In addition, Usher and Morrison point to the economic shifts in these areas, which were once dominated by community organizations and businesses operated by LGBTQ community members but have been increasingly commercialized by mainstream businesses that have driven up rent prices and driven out long-standing neighborhood institutions. While the emerging role of online communities in the LGBTQ community may replace physical LGBTQ space, these changes also elicit questions about the possible detriment of culture-building and collective action when such physical spaces are no longer present.

LGBTQ Families: Marriage and Parenting Legislation

One source of significant change in the LGBTQ community is the evolving legislation regarding rights related to gender and sexuality, in particular, marriage and parenting rights. Marriage is the more visible of these two areas, with same-sex marriage laws having been passed in 17 states and the District of Columbia and civil unions and domestic partnerships legalized in several others since Vermont passed the first civil union law in 2000. Recent attention has been turned to the current federal marriage law in the form of the Defense of Marriage Act, which restricted the definition of marriage to one man and one woman and prohibited the recognition of same-sex unions at the federal level, and the Supreme Court's decision to hear a case arguing the law's unconstitutionality (Condon, 2012). In 11 states and the District of Columbia, adoption of an unmarried partner's child, termed 'second-parent adoption,' is protected under law, and in states where same-sex relationships are recognized legally, parents can access rights afforded to married couples such as stepparent adoption. In some other states, second-parent adoption is not protected by law but is legally recognized. In the remaining states, no legal avenues for second-parent adoption exist. The ramifications of these laws are manifold; issues range from access to a partner's insurance benefits to child custody in the case of injury or death, and they also set cultural standards of inequality by prizing some relationships (legally recognized) over others that are not deemed as valid.

Marriage and parenting rights legislation for LGBTQ families has resulted in steps toward equal rights for members of this community, but the larger movement has also spurred some anti-LGBTQ legislation. Those lobbying against LGBTQ rights or on behalf of anti-LGBTQ legislation may enlist rhetoric that magnifies existing heterosexist attitudes. The families of LGBTQ individuals may be delegitimized in comparison to traditional families (Peterson, 2011) or attacked as less fit or unfit to parent, despite a plethora of research demonstrating otherwise (for a review, see Patterson, 2009).

A growing body of research has investigated the impact of legislative campaigns concerning LGBTQ rights on members of the community. These legal battles are not without consequences for community members and have been associated with increased negative affect, depressive symptoms, and increased stress (Rostosky et al., 2009; Russell, 2004), and experience of negative outcomes has been found among family members of LGBT individuals as well (Arm et al., 2009; Horne et al., 2011). The stressors associated with these legal battles for LGB individuals include facing increased homophobia, increased vigilance, and experiences of division within communities (Russell and Richards, 2003). On the other hand, participation in activism for LGBTQ rights has also been associated with benefits and is considered a means of coping with the experience of discrimination and harassment (Riggle et al., 2010).

In addition to changes in legislation specific to LGBTQ rights, broader social changes have also molded the landscape of family life for heterosexuals and LGBTQ individuals alike. Weeks et al.'s (2001) text, for which they interviewed British LGBTQ men and women, put the contemporary experience of these individuals in the context of the history of families of choice and dominant conceptualizations of family and found space for both similarities with and differences between LGBTQ and heterosexual individuals. Weeks et al. emphasize the freedom that their participants voiced in regards to their experience of family; having been marginalized from dominant conceptualizations of family life, participants were freed from the expectations that come with these ideas and could create their own kind of family instead. In addition, the authors note that both the traditional nuclear family structure and heterosexism, while still predominant, have been increasingly challenged on a societal level, and it is in the context of these changes that contemporary LGBTQ individuals have begun to expand notions of families of choice. Weeks et al. also emphasize a tension between the pressure to embrace traditional family forms and the discomfort or rejection by others experienced as a result of an understanding of marriage and family as cultural institutions that have long been used to demarcate LGBTQ individuals as 'other.'

Parenting by LGBTQ Individuals

Raising children is one aspect of LGBTQ family life that has changed in myriad and creative ways. Whereas at one time many LGBTQ individuals, couples, and other family structures were given no avenue for planning to have children or acknowledge their parental status as openly LGBTQ people, LGBTQ community members are increasingly planning families and raising children openly. A recent Williams Institute analysis reported that an estimated 37% of adults who identify as LGBT have had a child during their lives, and an estimated 19% of current same-sex households include children (Gates, 2013). While these statistics should be read with caution due to the challenges inherent to accurate measurement of the LGBTQ population and the limitation of the sample to couples and households only, they provide some sense of the number of individuals who are navigating the complexities of LGBTQ parenting.

Recent data also suggest that same-sex couples are four times more likely to be raising an adopted child than different-sex parents, and they are six times more likely to be raising foster children (Gates, 2013). The data also suggest that the majority of children raised by same-sex couples are biological or 'step' children, forming what are often termed 'gay stepfamilies.'

Indeed, LGBTQ individuals are becoming parents in a diversity of ways. Patterson and Riskind (2010) provide an excellent review of the literature on the ways in which LGBTQ individuals seek pathways to parenting that include stepfamilies, surrogacy, artificial insemination, fostering and adoption, coparenting, and others, as well as the potentially shifting attitudes toward parenting among community members (see also Green, 2012; Tasker and Patterson, 2007). These trends may suggest the LGBTQ parents who participated in these surveys are increasingly planning children within the context of their relationships, as community members increasingly 'come out' earlier in life (Floyd and Bakeman, 2006) and more avenues for parenting become available.

Yet becoming a parent is by no means easy for LGBTQ persons. Scholars have begun to explore the complexity of the LGBTQ parent experience, including both the aspects of it that are universal for parents and others that are unique to negotiations of systems and relationships that offer differing levels of support specific to gender and sexuality issues (Goldberg, 2010, 2012; Goldberg and Allen, 2012; Hines, 2006; Ryan and Berkowitz, 2009). Parents report encountering heterosexism and discrimination both in institutions and relationships. For many, the need to integrate a parenting identity with their sexual and gender identities is a process because parenting is not necessarily an assumed or 'natural' rite in dominant conceptualizations of minority sexuality. Whereas being 'out' with one's identity is often assumed to be an indication of healthy development, disclosure takes on new meaning for LGBTQ persons who become parents and must navigate interactions with agencies, schools, health care settings, government offices, and other organizations and balance the needs and safety of their children against the price of concealment of identity (Tasker and Patterson, 2007). Further, parenting via biological means is often assumed and given precedence, providing an additional challenge for parents who parent through adoption or stepparenting or other means.

These accounts highlight the ways in which LGBTQ parents are navigating uncharted territory and the benefits of their own resiliency and the support of others. Yet many parents report that some of their friendships within the LGBTQ community weaken or dissolve after becoming a parent and that instead, friendships with other parents who are heterosexual are formed (Goldberg, 2012; Green, 2012). These shifts may reflect differing attitudes toward parenting across LGBTQ and heterosexual communities and/or the prioritization of a parenting identity over sexual or gender identity. Parents have also noted that their transitions to parenthood were accompanied by changes in relationships within their families of origin, including both positive and negative ones.

Conclusion

The history of family for LGBTQ individuals communicates, above all, that the need for the love and support offered by family bonds is a universal one. While members of this community historically have not been provided with opportunities to experience family as it is most popularly conceived, they have nonetheless found ways to establish lasting bonds through families of choice. LGBTQ individuals continue to face heterosexism, discrimination, and harassment on the basis of their gender and sexuality today, but as acceptance of LGBTQ persons has increased and legal recognition of the right to experience traditional or constructed family life has begun to be a reality, the meaning of 'family' in the LGBTQ community has continued to evolve. In order to support the LGBTQ community in its diversity, this transition needs to include the right for all LGBTQ individuals to choose their preferred form of family, including both those arrangements that resemble the

traditional family as well as the novel and rich forms of chosen families commonly found in LGBTQ communities.

Sexual Motivation

Martha K McClintock, The Institute for Mind and Biology, The University of Chicago, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

As in other mammals, human motivation has multiple components each based on different neuroendocrine mechanisms. Its components are tightly integrated in young and middle adulthood, yet develop and age at different times. Thus they are most easily recognized as separable components during childhood and older ages, and in clinical complaints. The components are sexual sensorimotor reflexes and pleasure, gender identity, sexual attractiveness, sexual valence and salience, sexual receptivity, and proactive sexual desire.

Human sexual motivation is a pleasurable subjective state felt by people as sexual desire, libido, lust, sexual interest, drive, passion, and craving (Giles, 2008). It causes a person to act sexually, guides behavior toward achieving sexual goals, to seek sexual objects and partners and persevere when they are not attained. Yet, sexual motivation does not necessarily culminate in sexual behavior, and, in psychoanalytic theory (Freud, 1930), is a force that can be denied or repressed, and also sublimated into positive activities unrelated to sexuality.

Adult sexual motivation is not monolithic. It has multiple components, which are so tightly coupled in adults that it is hard to imagine one without the others. Yet, these components do not develop at the same time, and from birth to adulthood their developmental unfolding reveals that they are indeed separable (McClintock, 2009). Moreover, neuroendocrine and behavioral research in animals reveals that the multiple components have different brain and hormonal mechanisms. In developmental order, they are as follows: (1) *sexual sensorimotor function* enabling genital arousal, sexual responses, and sensuality; (2) *gender identity*, necessary for acquiring both culturally appropriate sex roles including gender-specific sexual behavior and attitudes; (3) *sexual attractiveness*, culturally specific efforts to make oneself sexually attractive to others; (4) *sexual valence or salience*, perceiving particular people, things, or stimuli as sexually attractive, that is, perceiving a person, an image, a song, or any number of things as erotic; (5) *sexual receptivity*, which is the consent and willingness to engage in intimate sexual behavior with another person; and (6) *proactive sexual desire*, that is, wanting and seeking out sexual interactions with another person or oneself.

Sexual motivation arises from a nexus of biological forces, both physiological and evolutionary, psychological emotions and beliefs and molding by social context and cultural constructs. This article reviews the evidence that these biological, psychological, and social forces play different roles for each of the components, again demonstrating that they are separable parts of a functioning whole. The social, behavioral, and neuroendocrine mechanisms of sexual motivation have been explicated extensively in many vertebrate species and manifest many communalities.

Males typically have the capacity to mate at anytime during a breeding season, whereas female mating and sexual motivation is closely tied to a fertile state, whether it is going into heat or ovulating reflexively in response to mating behavior. Human sexual behavior, and that of a few other primates (Fürtbauer et al., 2011; Wallen, 1990), is notable because women can have sex at any time. This evolutionary advance means that pleasure, recreation, and intimacy are additional important functions of sexual motivation, certainly changing and expanding the relative contributions of biology, psychology, and social context. Where possible, differences and similarities between men and women will be noted, as well as variation within each gender.

Sexual Sensorimotor Function

Sexual sensorimotor function is the most foundational component of sexual motivation, in both developmental and evolutionary time frames. Genital stimulation is pleasurable and motivating. Penile erections are sexual reflexes highly conserved across mammals and many vertebrates. In people, erections develop *in utero* and are obviously frequent in newborn boys, indicating intact spinal reflex arcs (Giuliano and Rampin, 2004). A balance of inhibitory and excitatory brain mechanisms regulates erections. In male rats, the classic model for erectile function in men, the paraventricular nucleus of the hypothalamus is key, integrating information from central and autonomic nervous systems and projecting to the brainstem and spinal cord (Argiolas and Melis, 2005). These oxytocin-containing neurons are modulated by a complex set of interacting compounds including testosterone and neuropeptides such as dopamine, GABA, hexarelin, pro-VGF-derived peptides, and potentially melanocortin (Argiolas and Melis, 2003; Shadiack et al., 2007).

A girl's clitoris develops from the same embryological tissue as the penis (Shafik, 1993). Although unstudied, it is likely that clitoral erections also develop early, and even in adulthood, there is a paucity of research; as of 2014, there had been only 32 research articles on clitoral erections listed in PubMed, in striking contrast to 7586 on penile erections. Likewise, the scrotum and labia develop from the same embryological tissue and are homologous structures responding erotically to touch (Puppo, 2013).

These erections and pleasurable genital sensations are initially elicited by many types of touch and stimuli: clothing, moving air, a nursing mother, a caregiver cleaning genitals, and by infants themselves as they begin to explore their own

unclothed bodies. Toddlers masturbate, continuing through age 5 (Bancroft, 2003; Sandfort and Rademakers, 2000) when the practice wanes. At this young age, masturbation is focused on pleasurable physical genital sensations without a sexual relationship or object of desire, and without the other components of adult sexual motivation such as being sexually receptive to another person. Again, there has been little investigation of the role of masturbation in the development of sexuality in girls (Whitfield, 1989).

In mammals, touch and genital responses in infancy and juvenescence are essential for developing normal adult sexual motivation in both males and females (Cooke et al., 2000; Lenz et al., 2008). Clitoral stimulation in rats is rewarding (Parada et al., 2010), supporting the theory that it plays an important role in the genital sensorimotor component of sexual motivation, although Wallen and Lloyd (2008) argue it has no adaptive advantage. Nonetheless, in humans, these pleasurable sensations and sexual reflexes in infancy and childhood likely undergird the adult sexual sensorimotor reflexes studied in exquisite detail by the pioneering work of Masters and Johnson (1966) and recently elaborated by Argiolas and Melis (2003), Basson (2001), and Hyde et al. (2012).

Social context obviously plays a strong role linking the inherently pleasurable and motivating genital sensations with other components of sexual motivation emerging in adolescence and adulthood. In male rats, juvenile social isolation impairs adult sexual behavior (Cooke et al., 2000). In many cultures and social classes, infants discovering pleasant genital sensations are not heavily discouraged, while in others, genital stimulation is shameful and disgraceful, if not taboo, particularly for girls. Thus, from an early age, the interplay between biological reflexive genital responses and strong cultural and moral views shape adult sexual responses and motivation.

Gender Identity

Gender identity as a boy/man or girl/woman enables acquisition of gender-specific sexual motivation, attitudes, and behavior, a learning process that continues throughout adulthood. Gender identity itself, however, does not appear to be learned. Rather, the current view is that it is determined prenatally, likely by testosterone which masculinizes the brain long after and independently of its masculinizing the genitals (Bao and Swaab, 2011).

This is not to argue pure biological determinism. Social and cultural factors do play a large role, establishing what sexual identities and behaviors are considered normative, natural variants, or taboo. Awareness of different kinds of genitals, and ultimately categorizing other people and oneself based on having a penis or a vagina is a learned cultural norm. Interestingly, learning the distinctions appears to develop independently of children's pleasure in their own genital sensations, albeit at similar ages (Bancroft, 2003).

One of the more dramatic examples of the role of social context comes from cultural comparison of people with 5-alpha-reductase deficiency, which causes genetic males (XY) to be categorized as girls at birth because they have labia and a clitoris. At puberty their sex organs change dramatically. Their testes descend and the clitoris enlarges into a penis, enabling adults to father children. Among the Sambia of New Guinea, where this genetic variation is common, it is accepted that some people are men, some women, and others are 'kwolu-aatmwol,' the gender of people born as girls who change to men at puberty, a gender which confers status as a shaman (Herdt, 1990). In the Dominican Republic, where the genetic variant is also common, it was simply accepted before cultural contact with western researchers that some people change gender at puberty. After contact, the Western view of the United States and Europe prevailed, and such people are now viewed as suffering from a pathological type of sexual development and gender dysphoria. Thus social context and culture shapes the meaning of biological mechanisms, determining how an individual experiences their gender identity and orientation, which contributes to the development of sexual motivations that drive their behavior.

Sexual Attractiveness

The desire to *be sexually attractive* to other people is another aspect of sexual motivation (also termed *attractivity*), that is, to arouse sexual desire in others or have sex appeal. Sexual coloration and displays in animals that reproduce sexually are often dramatic and effective in attracting healthier, more fertile, and more parental mates. North African Houbara bustards display dramatic plumage while running and 'booming' to attract mates; male bowerbirds adjust their built bowers and behavioral displays based on responses to the female (Patricelli et al., 2002). Likewise, there is growing evidence that female showiness affects male mate choice (Amundsen, 2000). Female hummingbirds defend a larger and more attractive territory with colorful and energetic displays; among female redwing blackbirds, the intensity of the red epaulets reflects their health condition. But showiness can come at a cost, even though it is a more effective mating strategy; male Houbara bustards with the more dramatic displays age faster than less showy males.

Humans in particular employ a wide range of behaviors to increase their sexual attractiveness, either to a potential sexual partner or socially. Language, of course, depends entirely on social context and culture, but so do nonverbal behaviors including dress and adornments, cosmetics, gestures, eye contact, facial expressions, posture and gait, even displaying altruistic behavior (Barclay, 2010; Elliot and Pazda, 2012; Knapp et al., 2014; Moore, 2010; Townsend and Wasserman, 1997). Often these nonverbal behaviors emphasize the physical traits that distinguish the two sexes, such as waist to hip ratio and musculature, which are more universal cross culturally in their sexual appeal (Singh, 2004; Dixson et al., 2010).

Attractivity and sexual signaling begins developing early in childhood, between ages 3 and 6, when boys often 'flirt' with their mothers and girls with their father, as noted by Freud (1949). Again, sexual attractiveness is developing well before a child has any concept of actively seeking a sexual partner. With time, however, planning and becoming sexually attractive becomes more than a simple 'drive.' It must involve the cerebral cortex, particularly executive function in the prefrontal cortex (PFC), and is modulated by gonadal hormones (Durante et al., 2008; Grammer et al., 2004; Kalat, 2007).

Sexual Valence and Salience

Noticing and feeling that another person is sexually attractive means that they are perceived with a sexual valence, becoming salient and standing out from all others. *Sexual valence and salience* is essential for sexual arousal, which is increasingly viewed as a responsive process to stimuli, rather than a spontaneous, internal drive (Basson, 2001; Both et al., 2011). In motivational theory, people or things that are sexually attractive are termed 'incentive stimuli' imbued with a positive valence, eliciting 'wanting' and activating approach (Hernández-González et al., 2008).

Sexual valence and salience of other people first develops around the age of 10, before puberty is culturally recognized in the United States. At this age, the first memorable sexual attraction or 'crush' may be for a peer, a teacher, or a movie star (McClintock and Herdt, 1996; McClintock, 2009). On average, boys and girls have this experience at the same age (ranging from 6 to 15 years of age), despite the 2-year sex difference in pubertal development between girls and boys (Herdt and McClintock, 2000). Moreover, people with a homosexual orientation also report that this was the age of their first sexual attraction, despite strong social sanctions to be heterosexual.

Maturation of the adrenal glands, or adrenarche, occurs around age 10, and production of the androgen dehydroepiandrosterone rises into the adult range stimulating pubic hair growth and also allowing the experience of finding someone else sexually attractive to become memorable.

The current view is that sexual orientation, i.e., being gay, straight, or bisexual, is typically determined prenatally (but by a different set of neuroendocrine mechanisms than determine gender identity, Bao and Swaab, 2011). Around 10 years of age, the adrenal hormonal milieu activates these prenatally determined brain circuits, and the objects of one's desire become salient, well before a child has developed the proactive sexual motivation or behavior that will later emerge in adolescence. As adults, not only do gays find pictures of same-sex swimsuit models more sexually attractive than the opposite sex, which are attractive to straight heterosexuals, but self-identified bisexuals find both men and women models sexually attractive (Lippa, 2013).

There are sex differences in brain circuits processing such visual sexual stimuli in adults, with men exhibiting greater metabolic activity in the amygdale than do women (Hamann et al., 2004). Women, however, may have been understimulated in this study, being more sensitive to contextual stimuli, particularly emotional expressions of an affectionate relationship (Leitenberg and Henning, 1995; Rupp and Wallen, 2008) as well as observational stance (participant vs observer, Both et al., 2011; Bossio et al., 2014). Nonetheless, there is consistent neurological evidence for sex differences in responses to sexual stimuli (Karama et al., 2002) as well as effects of gonadal steroids such as testosterone and estradiol (Alexander and Sherwin, 1993; Roney and Simmons, 2008; Rupp et al., 2009; Welling et al., 2007, 2008). In all studies, including neuroendocrine studies of rodent models, the PFC is critical for processing sexual valence and salience. In the rat, it is the orbital PFC that participates in the processing of olfactory sexual signals, while the medial PFC is involved in motive-emotional processing, temporal sequencing, and memory (Hernández-González et al., 2008).

Sexual Receptivity

Sexual receptivity is the willingness to have sex with a partner when given the opportunity. People, particularly women, can be sexually receptive prior to being sexually aroused (the genital sensorimotor component). In this case, arousal builds afterward during sexual activity, rather than before it. This sequence of components contrasts with Masters and Johnson's classic unidirectional linear model of sexual behavior in which desire precedes being receptive and sexual arousal. The need to reconceptualize sexual motivation has been driven by the fact that women in particular may be receptive to engaging in sexual activity for a variety of reasons different from sexual desire or arousal, such as a need for emotional closeness, gratitude, duty, or payment (Basson, 2000; Meston, 2001).

In women, cultural context has different effects on sexual receptivity and its relationship with the other components of sexual motivation. East Asian women living in Canada are less likely than Euro-Canadians to report being sexually receptive to their partners. Among East Asian women, mainstream acculturation is not associated with greater sexual receptivity even though acculturation is associated with greater sexual arousal. Perhaps the East Asian women in these studies were less comfortable reporting sexual receptivity than arousal. Nonetheless, the relative resistance of sexual receptivity to Westernization is striking.

In contrast, the first study of sexuality of Indian women reveals that their sexual receptivity is high. Among 100 married Indian women, fully 75% reported accepting their husband's sexual advances with pleasure, although none initiated sexual activity (Avasthi et al., 2008). Married Han women in mainland China exhibited a different pattern. Greater sexual receptivity was associated with more sexual initiation (Han et al., 2014). Taken together, this cross-cultural comparison supports the independence of sexual receptivity from other components of sexual motivation such as arousal and sexual initiation.

Elegant neuroendocrine research in mammals has elucidated the mechanisms of sexual receptivity, focusing on the female's adopting a mating posture in response to the male, rather than fighting him off. In many species, this is a lordosis reflex, which raises the vagina to facilitate copulation. This reflex is enhanced by estrogen released by ripening ovarian follicles that act peripherally to enlarge the genital sensory field. It also binds in neurons of the ventrolateral portion of the ventromedial hypothalamus, part of a well-characterized system including the posterodorsal medial amygdala, bed nucleus of the stria terminalis, medial preoptic nucleus, and the arcuate nucleus (Micevych and Dewing, 2011). The reflex is regulated within this system by a panoply of neuropeptides including glutamate, GABA, oxytocin, cholecystokinin, and generalized CNS arousal, such as norepinephrine (Flanagan-Cato, 2011; Lee and Pfaff, 2008).

The cultural and neuroendocrine mechanisms of sexual receptivity in men and in male animal models is understudied, perhaps because it plays a small role, but more likely reflecting

a cultural bias. In Soay sheep, rams are more receptive to some ewes that are in heat than others, and thereby choose a mate. Male rats and mice are also more receptive to some females than others, exhibiting large individual differences in how responsive they are to a female in heat (Bharadwaj et al., 2013; McClintock and Adler, 1978).

Proactive Sexual Desire and Solicitation

Proactive sexual desire is not only wanting the reward of erotic pleasure but also making an effort to initiate sexual activity with a partner or by masturbating. Historically, the focus of neuroendocrine research had been on the 'appetitive' sexual motivation of male rodents and not on females. It then became evident that female rodents also actively solicit mating, in addition to being receptive to the male's advances, and actively pace copulation, competing to get the ejaculate of particular males (McClintock, 1984). A new term, 'proceptive,' was proposed for this behavior, as if the female's active sexual motivation was somehow different from the male. A better solution is employing 'proactive sexual desire' as a gender-neutral alternative to reference actively seeking erotic sexual activity by either males or females.

In females, proactive sexual desire has different neuroendocrine mechanisms than sexual receptivity in rodents, nonhuman primates, and humans (Coria-Avila and Pfaus, 2007; López et al., 2009). In female rodents, progesterone from the ovary and brain, in addition to estradiol, plays a key role in acting on the preoptic nucleus (Micevych and Dewing, 2011; Sakuma, 1995). Proceptive solicitation relies on an intact preoptic area, whereas its ablation enhances lordosis, the receptive component. Comparably detailed neuroendocrine mechanisms distinguishing male receptive and proactive sexual motivation have not been done because male receptivity is understudied.

Ovarian hormones also increase proactive sexual desire in women. During the preovulatory sexual phase of the menstrual cycle, women report increased sexual desire, sexual fantasies and dreams, and masturbation (Bullivant et al., 2004; Gangestad and Thornhill, 2008; Tarín and Gómez-Piquer, 2002). However, in sharp contrast to mammals that must be in heat to actively seek mating, this periovulatory increase in women is superimposed on proactive sexual desire sustained levels throughout the ovulatory menstrual cycle. Likewise, in female nonhuman primates that also mate when not fertile, sexual initiation, rather than copulation, is arguably the best behavioral indicator of female proactive sexual desire (Wallen, 1990, 2013).

In hypogonadal men, testosterone increases sexual desire (Finkelstein et al., 2013) as it does in most male mammals. Likewise, testosterone regulates proactive sexual motivation in male rats (Ågmo, 2003; Hamson and Watson, 2004), increasing dendritic spine number of neurons in the medial preoptic area of the hypothalamus in Syrian hamsters (Garelick and Swann, 2014). Androgens may also contribute to women's sexual desire. They are produced tonically in women, as they are in men, from both the ovary and the adrenal. They rise slightly prior to ovulation. As a drug, they benefit some women suffering from hypoactive sexual desire (Davis and Worsley, 2013). However, androgens are not sufficient as they are in men, and their effects on sexual desire require a background of estradiol (Wallen, 2013).

In men and women, testosterone and social interactions with potential partners form a positive feedback loop. Brief social interactions with young women increase testosterone in men, which in turn increases desire (Roney et al., 2003; Roney et al., 2007). Likewise in women, watching the courtship of an attractive man raises their testosterone (López et al., 2009), affecting their sexual desire as well.

Evolutionary theory posits that the sex (i.e., male or female) with less investment in conception and parenting will have higher levels of proactive sexual behaviors than the sex with a large investment, which will benefit by being more selective and choosing their partner, often by being receptive or not. In many mammals, the male fills this role, and is evident among people in many settings (Avasthi et al., 2008; Hendrie et al., 2009).

Women also initiate sociosexual encounters verbally and nonverbally, with a variety of culturally specific behaviors. In the contemporary United States, such behaviors include leaning forward, showing a palm, primping, short darting glance, lip lick, caressing an object, and head toss (Moore, 2002; Perper and Weis, 1987). These behaviors are more common around the time of ovulation even when women are unaware of their own fertile state.

Hormones and other compounds affecting sexuality can have a stronger effect on sexual desire and fantasies, measures of their motivation, rather than on sexual activity, which is obviously constrained by the availability of a sexual partner (Spencer et al., 2004). Likewise, partner availability determines whether proactive sexual motivation is experienced as desire or fantasies. If a woman has a regular sexual partner, then increased sexual motivation can be experienced as a desire for that particular partner. If without a partner, then she is more likely to create one through sexual fantasy.

Sexual desire develops around puberty in both boys and girls, manifest as 'wet dreams.' In girls, they are likely more common around the time of ovulation, as they are in women. But again, understanding at what age such dreams begin is a taboo topic, particularly in girls, precluding research on this natural marker of coordination among components of sexual motivation.

Biologically, puberty lasts a long time, during which the components of sexual motivation become fully integrated. It begins before the first ejaculate and menses that herald the capacity to conceive children and does not end until peak reproductive maturity is attained in the late teens or early 20s, and in women technically not until the first pregnancy and lactation. The capacity for partnerships and social roles develop and become intertwined with all components of sexual motivation, laying the foundation for resilient sexuality that can be sustained through diverse lifespan trajectories and into old age.

Diverse Scales for Measuring Human Sexual Motivation in Men and Women

The ideal study of human sexual motivation would measure each of its distinct components within a person. Simultaneous measurements would reveal the interactions among the components, as well as their differential sensitivity to a person's

cultural, social, psychological, and biological milieu. At the moment, there is no single scale for measuring all components of sexual motivation. Nonetheless, scales have been published for each of the components; Table 1 is arrayed to highlight each component of sexual motivation and to list the published scales focused on that component. Rather than arguing that some types of scales are better than others, a more profitable approach recognizes that they are often focused on different components. Ideally, future research will create a composite scale to enable the simultaneous study of multiple components.

The extant scales are often gender specific and focus on the most common clinical complaints by men and women. For men, the most common focus is on the sensorimotor component, particularly erectile dysfunction and premature ejaculation. For women, scales focus on disorders of hypoactive sexual desire, with only a few distinguishing between the receptive and proactive components of sexual motivation (see Table 1). Modifications of the scales would include sensorimotor questions appropriate for women and clearly distinguish the receptive and proactive components in both men and women.

The power of this approach is demonstrated by the scales that do include items assessing both the sexual sensorimotor component and the proactive sexual desire component, sometimes including receptivity (see Table 1). Among women, the multidimensional structure of the scales distinguished women with and without sexual difficulties. For example, in a normal population, orgasm frequency and ease (the sensorimotor reward driving sexual motivation) was the biggest contributor to the largest factor (eigen value 9.06), but contributed only to a much smaller factor (eigen value = 1.87) among women with sexual dysfunction. Sexual arousal was part of the largest factor in both groups, but among normal women arousal was associated with orgasm while it was associated with desire among women with dysfunction (Wiegel et al., 2005).

There were also national/cultural differences in the factor structure. In Chinese Han women of mainland China, frequency of sexual thoughts were not associated with desire, as they were in a North American population, but rather constituted a smaller factor explaining only 7.66% of the variance. Thus, the reported lower sexual desire among Canadian Asian women may result from utilizing the North American subscale which combines reported desire with thoughts and fantasies. That is, the levels of desire may well be the same, but not expressed as reporting sexual fantasies and thoughts.

Even when measuring the same aspect of sexual motivation, some scales frame items positively and others as a dysfunction. The BISF-W asks "how frequently have you become aroused during the following activities?" (Mazer et al., 2000). The Natsal-SF asks, if you have "felt no excitement or arousal during sex" for a period of 3 months or longer (Mitchell et al., 2012). The BISF-W is thus better suited to assessing a wide range of variation in normal sexual function as well as dysfunction, whereas the Natsal-SF focuses on prevalence of sexual problems.

The scales designed for both men and women typically focus on sexual difficulties. In the sensorimotor component, these included impotence, poor physical arousal, trouble lubricating, and problems with orgasm. The proactive component is assessed by questions about lacking sexual enjoyment or desire. Positive elements included sexual thoughts and drive (see Table 1).

The other components of sexual motivation are not included in general scales for sexual motivation. Thus, separate scales are necessary for each. Gender identity is well measured by Freund's scales, assessing variation in behaviors, self-concept, and wishes typical of the opposite sex (see Table 1). Barelds et al. (2011) developed a scale to measure how physically attractive a person perceives themselves to be as well as to their partner and the general public. Diamond (2011) measures sexual valence and salience, a key component of sexual orientation, not by asking about behavior as Kinsey did, but by focusing on sexual attraction to both men and women, providing a rich measure of a continuum of attraction including degrees of bisexuality.

Sexual receptivity is measured by specific items in scales by Mazer et al. (2000) and Han et al. (2014), although their coding system treats receptivity as part of a continuum with sexual initiation (see Table 1). Nonetheless, single item analyses are supported. Receptivity can also be measured by conceptualizing it in the context of Humphreys and Brousseau's Sexual Consent Scale (2010).

Finally, proactive sexual desire can be measured separately from direct questions about sexual sensorimotor arousal by assessing content of daydreams with the Sexual Daydreaming Scale (Purifoy et al., 1992). Recognizing that sexual assertiveness can be driven not only by sexual desire and motivation, but also by other motivations such as power and reinforcing emotional intimacy, Anderson and Newton (2011) developed the Sexually Assertive Behavior Scale to tease out these diverse motivations among women (see Table 1).

Summary and DSM 5

The argument for components of sexual motivation is strong. The components develop at different ages. They have different neuroendocrine mechanisms. There are strong cultural differences in the associations among components. One component may be dysfunctional while the others are intact. Even though men and women have all of the same components, there are sex differences in neuroendocrine mechanisms that support them and which are most vulnerable to dysfunction.

Nonetheless, the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM 5) has collapsed these components in their criteria for sexual dysfunction among women (IsHak and Gabriel, 2013). In DSM 4, the female disorders of arousal (sensorimotor component) and desire (proactive sexual desire component) were separate. The DSM 5 now has a single diagnosis called 'female sexual interest/arousal disorder.' This amalgamation was intended to recognize the striking sex difference in the temporal relationship between desire and arousal. In men, the pattern is typically linear, with desire preceding arousal, as described by Masters and Johnson (1966). In women, however, they can occur in the opposite sequence, building upon each other.

Not all on the DSM 5 committee agreed that this warranted combining these two components to define a single diagnostic category, especially because the category also includes the other components of sexual motivation delineated in this article: few erotic thoughts or fantasies, low initiation of sexual activity, low responsiveness to a partner's sexual

Table 1 Scales for measuring components of sexual motivation

Scales					*Components of sexual motivation*					
Scale name	*Reference*	*Gender*	*Target population*	*Composite score*	*Sexual sensorimotor function*	*Gender identity*	*Sexual attractiveness*	*Sexual valence and salience*	*Sexual receptivity*	*Proactive sexual desire solicitation*
Brief Index of Sexual Functioning of Women (BISF–W) updated	Mazer et al., 2000; based on Taylor Rosen and Leiblum, 1994	Women	North American, with and without sexual dysfunction	Norms available	Arousal; pleasure/orgasm; difficulties	N.A.	N.A.	N.A.	Thoughts/desire (D1), receptivity/initiation combined (D4): initiation(8), receptivity (9), and desired frequency (12)	
Chinese Brief Index of Sexual Functioning of Women (C-BISF-W)	Han et al., 2014	Women	Mainland China, with and without depression	Validated	Arousal; orgasm; difficulties	N.A.	N.A.	N.A.	Desire only (D1), receptivity/initiation (D6) also includes experiencing pleasure (10) and being able to communicate desires (17)	
Female Sexual Function Index (FSFI)	Wiegel et al., 2005	Women	North American clinic, with and without sexual dysfunction	Reliability, convergent, and discriminant validity	Arousal/orgasm, lubrication, pain;	N.A.	N.A.	N.A.	N.A.	Desire/arousal
British National Survey of Sexual Attitudes and Lifestyles-Sexual Function (Natsal-SF)	Mitchell et al., 2012	Men and women	Survey of community dwellers in Britain	Validates with general population and clinical samples	Negative items; no excitement, trouble with climax	N.A.	N.A.	N.A.	N.A.	Negative items, lacked enjoyment or interest
Derogatis Interview for Sexual Functioning (DISF)	Derogatis and Melisaratos, 1979	Men and women	North American and European community norms	Validated	Arousal, orgasm	N.A.	N.A.	N.A.	N.A.	Thoughts, sex drive
Detailed Assessment of Sexual Arousal (DASA)	Basson and Brotto, 2003	Men and women	North American clinic, with and without sexual dysfunction	Screener	Subjective, pleasure and physical arousal	N.A.	N.A.	N.A.	N.A.	N.A.

Feminine Gender Identity Scale (FGIS)	Freund et al., 1977	Men	North American heterosexuals, homosexuals, and MF transexuals	Validated	N.A.	Variation among men in behaviors, self-concept, and wishes	N.A.	N.A.	N.A.	N.A.
Masculine Gender Identity Scale for Females (MGISF)	Blanchard and Freund, 1983	Women	North American heterosexuals, homosexuals, and FM transexuals	Validated	N.A.	Variation among women in behaviors, self-concept, and wishes	N.A.	N.A.	N.A.	N.A.
Assessment of Attractiveness	Barelds et al., 2011	Men and women	Dutch heterosexual couples	Validated	N.A.	N.A.	Attractive to self, partner, and general population	N.A.	N.A.	N.A.
Assessing Multiple Facets of Attraction to Women and Men	Diamond, 2011	Men and women	North American heterosexuals and homosexuals	Validated	N.A.	N.A.	N.A.	Frequency and intensity of attraction to men and women	N.A.	N.A.
Sexual Consent Scale Revised (SCS-R)	Humphreys and Brousseau, 2010	Men and women	Heterosexual undergraduates North America	Validated	N.A.	N.A.	N.A.	N.A.	Consent to sexual invitation	N.A.
Sexual Daydreaming Scale	Purifoy et al., 1992	Men and women	Homosexual and heterosexual throughout lifespan	Validated	N.A.	N.A.	N.A.	N.A.	N.A.	Multiple facets of sexuality, correlated with daydreaming in general
Sexually Assertive Behavior Scale (SABS)	Anderson and Newton, 2011	Women	North American	Internal consistency, reliability	N.A.	N.A.	N.A.	N.A.	N.A.	Discriminates sexual and other motivations

invitation, low response to sexual cues whether genital or not, and low physical excitement and pleasure and being nonresponsive during sexual activity. Nonetheless, the diagnostic criteria require only three out of six symptoms, not all of them, recognizing that they are indeed separable. Therefore, the 'lumping' of the components of sexual motivation in DSM 5 emphasizes that they are normally tightly coupled in typical sexual functioning, and that dysfunction arises when they are no longer coordinated.

Abstract

The article on sexual orientation and the law tracks historical and recent developments in the area by explaining the historical contingency of sexual orientation, its overlap with issues of gender conformity, and ways that litigation and theoretical research have informed one another. It details the changing social construction of same-sex sexuality from sinful conduct to a maligned status in the late nineteenth century, to a neutral status in the mid-twentieth century, and finally to a focus on postidentity in the late twentieth and early twenty-first century. Discussing developments in various countries, the article first traces the way that litigators and theorists focused on challenging antisodomy laws in the 1980s and early 1990s. It then describes sexual orientation law's shifting focus toward family law issues on a global level, and particularly the push toward same-sex marriage. The article further describes various theoretical approaches to sexual orientation law. It explores contemporary frameworks and tensions in the field, in particular, the attempt to reconcile the postidentity approaches of postmodernism with the identity-based assumptions of conventional legal doctrine, the globalization of sexual and gender identity issues, and an increasing focus on the ways that transgender issues overlap and diverge from mainstream gay and lesbian concerns.

Introduction

The article on sexual orientation and the law tracks historical and recent developments in the area by explaining the historical contingency of sexual orientation, its overlap with issues of gender conformity, and ways that litigation and theoretical research have informed one another. It details the changing social construction of same-sex sexuality from sinful conduct to a maligned status in the late nineteenth century, to a neutral status in the mid-twentieth century, and finally to a focus on postidentity in the late twentieth and early twenty-first century. Discussing developments in various countries, the article first traces the way that litigators and theorists focused on challenging antisodomy laws in the 1980s and early 1990s. It then describes sexual orientation law's shifting focus toward family law issues on a global level, and particularly the push toward same-sex marriage. The article further describes various theoretical approaches to sexual orientation law. It explores contemporary frameworks and tensions in the field, in particular the attempt to reconcile the postidentity approaches of postmodernism with the identity-based assumptions of conventional legal doctrine, the globalization of sexual and gender identity issues, and an increasing focus on the ways that transgender issues overlap and diverge from mainstream gay and lesbian concerns.

Definitions of Sexual Orientation and Gender Identity

Sexual orientation refers to any classification based on sexual desire or conduct, such as heterosexuality, same-sex sexuality, or bisexuality. Sexual orientation describes an individual's physical or emotional attraction to the same or different gender, as well as attractions that may range along the gender spectrum or be variable over the course of one's lifetime (Diamond, 2008). Asexuality is also a sexual orientation, describing a low or absent sexual attraction to others. A person's sexual orientation is distinct from their gender identity and gender expression.

Gender identity refers to a person's internal sense of themselves as male or female (or potentially both or neither). This internal conception may not correspond to a person's body and the gender assigned at birth. Gender identity is self-defined, and emerges from a combination of inherent as well as environmental factors.

The term cisgender marks congruence between the gender one is assigned at birth, one's body, and one's lived experience of that gender; cisgendered people experience a match with societal expectations around their physical and mental expressions of gender identity.

A person who is transgendered experiences a gender identity that does not match up with the gender assigned at birth. Recent usage has favored the term 'trans*' to describe the broadest range of identities that fall outside the cisgender norm. This includes people who identify as transgender, transsexual, transvestite, genderqueer, genderless, two-spirit, and others. Usage without the asterisk generally refers explicitly to transgender men and women. The struggle for self-definition has been an important part of the trans* movement, with focus placed on the use of proper terminology as a symbol of respect and inclusivity. Being trans* does not imply any specific sexual orientation, and may involve identification as straight, gay, lesbian, or bisexual (or something else entirely).

Homosexuality and Heterosexuality as Historically Contingent

The study of the law relating to sexually marginalized people evolved in the 1980s and 1990s out of feminist legal theory, postmodern theory, and critical race theory. A major work informing what may be loosely termed as 'queer legal theory' is

Michel Foucault's *History of Sexuality*, vol. 1 (Foucault, 1978), which posited that sexual orientation is socially constructed rather than naturally or divinely ordained. This point has been further developed by Judith Butler's theory of gender performativity, which posits that identities such as gender are not static, but are produced and sustained through their constant reiteration and performance. (Butler, 1990).

From Conduct to Status to Belief

The social construction of sexual orientation is reflected by the shifting manner in which society and law have viewed same-sex sexuality. The different terms used to describe same-sex sexuality indicate these changes. Prior to the late nineteenth century, same-sex sexuality was viewed as sinful conduct, redeemable through repentance. The terms 'homosexual' and 'heterosexual' did not appear in English until 1892, along with the idea that sexual orientation was a status. These terms are products of German and English medical research on same-sex sexuality, which saw same-sex sexuality as a status, gave it a name, contrasted it with the previously unmarked status of heterosexuality, and assigned it social meaning as a constellation of characteristics based on what a person fundamentally *is* (rather than particular sexual acts that one *does*). As Foucault explains, "[H]omosexuality appeared as one of the forms of sexuality when it was transposed from the practice of sodomy into a kind of interior androgyny, a hermaphrodism of the soul. The sodomite had been a temporary aberration; the homosexual was now a species" (Foucault, 1978: 43). The terms 'invert' or 'homosexual' refer to this medicalized understanding of same-sex sexuality as a sickness rather than sinful conduct. Oscar Wilde's 1895 trials and imprisonment for gross indecency have been credited with introducing into popular culture the status of the male homosexual as effete, artistic, self-centered, and sybaritic (Ertman, 2000).

A third stage, beginning in the 1940s and 1950s, relied on the scientific research of Alfred Kinsey and Evelyn Hooker to contend that same-sex sexuality was a normal variation from opposite-sex sexuality, rather than a disease (Hooker, 1957; Kinsey et al., 1948). The nascent homophile movement adopted the term 'gay' to distance itself from the medical judgment associated with 'homosexual.' A fourth stage, emerging through LGBT (lesbian, gay, bisexual and transgender) and feminist poststructuralist studies in the early 1990s, rejected the very notion of sexual orientation status (evil, neutral or positive), pointing out the indeterminate and potentially subordinating qualities associated with status-based notions of identity. This stage dubbed minority sexual orientations 'queer' (reclaiming the epithet), treating this antistatus as an epistemological category. Queer theory, as this diverse field of study became known, arguably uncouples status from conduct, rejecting essentialist categories to the point that one person can be both queer and engaged in opposite-sex sexuality.

As a deconstructionist project, queer theory remains an intentionally inchoate discipline, definitionally unstable and often rejecting normative aims. This stands in contrast to legal scholarship, which even in its most critical formations, is often oriented toward normative questions and the pursuit of substantive remedies. This tension has made the development of 'queer legal theory' a difficult project. Janet Halley and Andrew Parker have pointed out that queer theory's failure to engage critical legal traditions, and especially the critique of rights, have generated a hostility in centrist legal studies to queer theoretical approaches that do not easily produce a 'policy recommendation' (Halley and Parker, 2007). This queer suspicion of law's essentialist categories has marked the move of LGBT rights into a global setting, with the concern that Western frameworks of gay, lesbian, bisexual, and trans* identity might not be appropriate or welcome in other cultural settings.

Changing Focus of Sexual Orientation Research

Sexual orientation law represents a synergy of gay rights advocacy and theoretical academic writings. Advocates bring cases and support legislation countering antigay discrimination. Scholars both craft theories that inform these efforts and evaluate the cases and statutes that become law. The process of legal reform around antigay discrimination has progressed in the twenty-first century toward an increasing social acceptance of lesbian and gay minorities within most Western, and many non-Western, states. This process requires a society to slowly move from a position of rejecting and persecuting its lesbian and gay minority to one of acceptance and respect by granting equal access to social and political opportunity as full citizens (Wintemute, 2011). It generally has evolved along the following path: (1) decriminalization of same-sex activity; (2) policies or laws prohibiting sexual orientation discrimination; and (3) reform of family law. In step with this process, two important historical areas for reform have involved the repeal of antisodomy laws and the state recognition of same-sex marriage.

Law and culture have also moved toward the recognition of transgender identities and nonbinary gender categories, with some states codifying the acknowledgment of 'third gender' options for self-identification. Nevertheless, substantial discrimination toward trans* individuals still remains. In the US, for example, transgender and gender-nonconforming people experience high rates of economic insecurity, with trans* people of color reporting especially devastating effects from antitransgender bias and persistent structural racism (Grant et al., 2011). Transgender law covers a range of issues related to discrimination in employment, education, immigration, and child custody decisions, as well as high rates of hate crimes and vulnerability to physical and sexual abuse in prison (Goodmark, 2013; Levi and Monnin-Browder, 2013; International Commission of Jurists, 2011). Rights to equality, privacy, and dignity have marked the jurisprudence on gender identity and gender recognition.

On a global level, many nations' courts have ruled against LGBT discrimination under both domestic constitutional rights and the discourse of international law and international human rights, as have transnational legal entities such as the European Union (Stychin, 2004). International documents have also been developed to address issues of sexual orientation and gender identity, most notably the Yogyakarta Principles on the Application of International Human Rights Law in relation to Sexual Orientation and Gender Identity. The

Principles were developed by a group of human rights experts and launched as a global charter for gay rights in 2007. They outline the application of international human rights law to sexual orientation and gender identity, affirming binding international legal standards with which all states must comply.

Antisodomy Laws

Because the criminalization of same-sex sexuality is the most obvious expression of state condemnation, sexual orientation law arose in challenges to antisodomy laws. Initially, much of the legal reform around the decriminalization of sodomy began legislatively. The 1957 Wolfenden Report in the UK proved an important turning point for criminal laws against sodomy. The report argued against equating the sphere of crime with that of sin, insisting that there must "remain a realm of private morality and immorality which is, in brief and crude terms, not the law's business." The Wolfenden recommendations were followed by the British government in 1967 through amendments to the *Sexual Offences Act*, and inspired the American Law Institute's proposal in the *Model Penal Code (MPC)* that states remove homosexuality from the list of offenses. While the *MPC* led a number of American states to repeal sodomy laws, many states nevertheless retained their bans on same-sex sexuality.

Advocates also challenged sodomy laws in court. In *Bowers v. Hardwick*, 478 US 186 (1986), the US Supreme Court upheld Georgia's statute criminalizing sodomy against a constitutional privacy challenge. In *Bowers*, the court declared that the constitution did not confer "a fundamental right to engage in homosexual sodomy." In a vivid concurring opinion, Chief Justice Burger wrote that to recognize sodomy as a fundamental right would be to 'cast aside millennia of moral teaching.' He cited Blackstone (1859) to describe same-sex sodomy as "an offense of 'deeper malignity' than rape, a heinous act 'the very mention of which is a disgrace to human nature.'" Other cases challenged discrimination against gays and lesbians, most notably *Romer v. Evans*, 517 U.S. 620 (1996), which struck down a Colorado constitutional provision that prevented gays and lesbians from obtaining protection against discrimination. The Court held that the provision's 'animus' toward gays and lesbians violated the Equal Protection Clause of the U.S. Constitution by making them "unequal to everyone else" and "a stranger to [Colorado's] laws." Nearly a decade later the Court returned to the issue in *Lawrence v. Texas*, 539 U.S. 558 (2003), which challenged a Texas statute that criminalized homosexual sodomy while leaving heterosexual sodomy legal in the state. The case was decided 5 to 4, overruling *Bowers* and concluding that the state lacked a legitimate interest in regulating the private sexual conduct of consenting adults. By holding that "the state cannot demean [same-sex couples'] existence or control their destiny by making their private sexual conduct a crime," *Lawrence* invalidated sodomy laws in the remaining 13 states that had them on the books.

Other governments have decriminalized same-sex sexuality and banned discrimination based on sexual orientation. The 1996 South African Constitution explicitly prohibited sexual orientation discrimination. The 2000 European Charter of Fundamental Rights includes explicit provisions against discrimination based on sexual orientation. Though the Charter is nonbinding, it frames the European vision on human rights. Several other states have protection against sexual orientation discrimination embedded in their constitutions including Ecuador, Canada, and Brazil, while countries like the Netherlands and Romania have sexual orientation antidiscrimination laws or articles in their Penal Code.

At the opposite extreme, the sodomy ban remains in force mainly in three categories of countries in Asia, Africa, and the English-speaking Caribbean as follows: (1) former colonies of the British Empire that inherited antisodomy legislation as part of English law; (2) countries with Muslim majorities that do not separate Islamic religious law from secular criminal law (the most populous exceptions to this pattern are Indonesia and Turkey); and (3) low-income and middle-income countries (Wintemute, 2011). In 2000 in Malaysia, for example, former deputy Prime Minister Anwar Ibrahim was convicted of sodomy and sentenced to 9 years in prison after a 14-month trial. In late 2013, the Supreme Court of India upheld the constitutionality of Section 377 of the Indian Penal Code, which criminalizes "carnal intercourse against the order of nature," overturning an intermediate appellate court decision. The Ugandan Parliament passed an 'Anti-Homosexuality Bill' in December 2013, which punishes sexual relations between persons of the same sex with a maximum penalty of life in prison.

The Ban on Same-Sex Marriage

Although antisodomy laws are rarely enforced, their existence impedes other antidiscrimination claims, such as gay people's rights to marry or to serve in the military. Advocates and legal scholars, however, have paid far more attention to marriage. Changes in family law around same-sex marriage have occurred through legislative change, judicial rulings based on constitutional guarantees of equality and by direct popular vote through ballot initiatives or referenda.

In 2001, the Netherlands became the first country to allow same-sex couples to marry. At the time of writing (early 2014), 15 other countries have followed suit, including Argentina, Belgium, Brazil, Britain, Canada, Denmark, France, Iceland, New Zealand, Norway, Portugal, South Africa, Spain, Sweden, and Uruguay. In Mexico, same-sex marriage is recognized in all states, but is only performed in three locations. Israel does not allow same-sex marriages to be performed, but does recognize marriages performed in permitting jurisdictions. Other countries offer many rights to same-sex couples but stop short of marriage, including Austria, Croatia, Czech Republic, Ecuador, Finland, Germany, Greenland, Hungary, Liechtenstein, Luxembourg, Slovenia, and Switzerland.

In the United States, starting with Massachusetts in 2003, a total of 19 states and the District of Columbia currently permit same-sex marriage. In 2013, the U.S. Supreme Court struck down as unconstitutional a key part of the Federal Defense of Marriage Act (DOMA), enacted by Congress in 1996, which defined marriage as a legal union between one man and woman. The Court in *United States v. Windsor*, 570 U.S. 12 (2013) held that this provision violated the Fifth Amendment's guarantee of equal protection of the laws because DOMA's purpose was to 'disparage and injure those

whom the state, by its marriage laws, sought to protect in personhood and dignity,' namely married same-sex couples.

Recognition of Gender Identity

While transgender law encompasses a complex range of issues, including health care, access to gender reassignment surgery, employment and housing discrimination, and transgender marriage, a major focus of advocacy and litigation has been on securing the legal recognition of one's preferred gender. Cases of legal recognition arise when trans* individuals seek to change their name or gender designations assigned at birth, and apply for the revision of official identity documents such as birth certificates, passports, and national identity cards (ICJ, 2011). As identification is required for many activities in daily life, the issue is significant, particularly for individuals with a gender presentation at odds with their identifying documents. In 2003, Australia became the first country to allow for a nonbinary designation of sex on a government passport, with a citizen claiming 'X' as their official gender marker rather than male or female. This indeterminate gender marker also became available to citizens of New Zealand in 2013.

Pakistan announced the recognition of a third gender designation on national census and identity cards in 2009, with Bangladesh and Nepal following suit in 2013. In April 2014, the Indian Supreme Court recognized transgender people as a legal third gender. Grounding its decision on rights guaranteed by the nation's Constitution as well as international law, the court determined gender identity to be fundamental to the rights to self-determination, dignity, and freedom. The judgment obliges central and state authorities to address the discrimination and stigma faced by transgender people, and grants individuals the right to legal recognition of their chosen gender identity (*National Legal Services Authority v. Union of India* [Writ Petition (Civil) No. 400 of 2012], delivered 15 April 2014).

Many countries now allow individuals to change their legal gender from male to female, or from female to male, although medical intervention (such as sex reassignment surgery) or psychological evaluation (such as a diagnosis of gender dysphoria) are required steps in most jurisdictions. The majority of European nations allow for name changes and revisions to designated sex on birth certificates, pending the submission of reports from a licensed medical practitioner. South Korea, Japan, and Malaysia also allow for transgender individuals to change their legal gender, although medical intervention is mandatory in most cases. In South Africa, the 2003 Alteration of Sex Description and Sex Status Act similarly permits the issuance of a new birth certificate and identity documents to transgender individuals who have undergone medical or surgical gender reassignment.

In the United States, the authority to determine issues of legal gender rests with the individual states. Idaho, Ohio, Kansas, Tennessee, and Oklahoma do not allow transgender people to change the gender marker on their birth certificate. Even in states such as California, Oregon, Vermont, and Washington that permit the change, however, different agencies follow different policies for the issuance of identity documents, requiring various medical, psychological, and surgical interventions and diagnoses. According to a 2011 study by the National Center for Transgender Equality, among those U.S. citizens who have transitioned gender, only 21% have been able to update all their identification documents and personal records and 33% have updated none of their IDs or records (Grant et al., 2011). Transgender individuals who cannot correct their documentation may face a greater risk of discrimination. In the same national study, 40% of people reported experiencing harassment when presenting identification that did not match their gender identity or expression, while 15% were asked to leave and 3% were attacked or assaulted.

Within the United States, discrimination based on a person's gender identity is increasingly prohibited, most notably in regard to employment facilities and gender-segregated facilities and/or activities. For instance, in the 2012 appeal *Macy v. Department of Justice*, the U.S. Equal Employment Opportunity Commission held that discrimination against an individual because that person is transgender (gender identity discrimination) is tantamount to sex discrimination and therefore prohibited under Title VII.

Theoretical Approaches to Sexual Orientation Law

The emphasis in current theory and research on sexual orientation law is to deconstruct and reconstruct legal regulations that subordinate gay and transgendered people. Under the rubric of theoretical approaches, we include both ideological and methodological approaches.

Ideology

There are diverse ideological approaches in the developing theory of sexual orientation law. A liberal approach would suggest that gay people are sufficiently similar to heterosexuals to justify equal legal treatment, and altering legal rules to allow same-sex marriage or openly gay military personnel will not fundamentally change these institutions. A critical approach, in contrast, contests essentialized notions of identity, seeing identity as socially constructed rather than reflecting essential commonalties among people who engage in same-sex sexuality. It may also critique the inequality inherent in institutions like marriage and the military. This kind of critical approach often seeks a more comprehensive restructuring of legal regulations than simply adding gay people to existing institutions, instead proposing the incorporation of sexual orientation analysis into other antisubordination discourses, such as feminism, critical race studies, and class analysis. Critical theorists might further propose alternatives to marriage, such as a range of relationship recognition devices for all families, including both couples and noncouples like close friends or adult sisters whose lives are intertwined (Polikoff, 2008; Rosenbury, 2007). These views contend that only new institutions can transcend essentialist notions of identity and alleviate the sex/gender hierarchies inherent in marriage.

Emerging Scholarship in Sexual Orientation and Gender Identity

Postmodern and empirical approaches have contributed to the literature on sexual orientation law. An influential queer

theoretical critique challenged the essentialism in immutability claims that are foundational to both legal doctrine and much gay and lesbian advocacy (Halley, 1994). An empirical study, in contrast, compiled data about rates of arrest and prosecution for sexual offenses to show that consensual same-sex sexual activity was unfairly singled out for criminal penalty (Eskridge, 1999). Both of these approaches have helped erode the legal and social legitimacy of criminalizing sodomy and build support for same-sex marriage and other reforms.

The most recent development in the field of law and sexuality has involved the construction of a global discourse of LGBT rights and political community. As LGBT causes found traction in law and policy in many Western nations, the focus of legal struggle has become increasingly internationalized. This shift has functioned to position LGBT rights as a new 'marker of modernity,' creating new political hierarchies and casting states that fail to respect rights around sexual diversity as 'backward and uncivilized' (Rao, 2011). Within these political hierarchies sexuality functions as a site of conflict and transfer point for power, with postcolonial states approaching the management of sex as a tool of governance – often in direct resistance to former colonial powers (Franke, 2004). These conflicts reveal the tension between cosmopolitan and communitarian perspectives, as well as intergenerational divides, the split between urban and rural dwellers, and between those who invoke a 'traditional past' unburdened by Western influences and those who claim a local history of pluralism and tolerance.

The importance of trans* voices and issues of gender identity have also gained increasing prominence in recent years. Critical politics around trans* issues have emerged from legal academia and activism, arguing for a broader agenda than mere law reform. As focused on the experiences of transgender and queer people, Dean Spade has called for attention to wide-ranging issues including "prison abolition, the elimination of poverty, access to full health care, and an end to immigration enforcement" (Spade, 2011). Such critical perspectives reflect the poststructuralist suspicions of law's normativity. They also evidence wariness of the civil rights and 'equality' strategies pursued by mainstream gay and lesbian advocacy organizations, criticizing their reliance upon state institutions of law and administration and their failure to account for the trans* bodies marginalized by such a legal rights framework.

This article is a revision of the previous edition by E. Stein, volume 21, pp. 13995–13998, © 2001, Elsevier Ltd.

Abstract

Research into the various influences on sexual orientation development has increased over the past 15–30 years. In this article, the key findings of the research into the biological influences on sexual orientation development are discussed. Specifically, biological influences are discussed in relation to prenatal hormones, genetics, the brain, the body, and the fraternal birth order effect. Future directions for research are also discussed and provide several fruitful lines of research for current and future researchers.

In 1973, 'homosexuality' was removed from the Diagnostic and Statistical Manual of Mental/Psychiatric Disorders. The removal of homosexuality as a mental disorder has had an impact on society, and has stimulated copious amounts of research on the complex trait of sexual orientation over the last 15–30 years. This research not only informs us about sexual dimorphisms (e.g., gender roles), atypical sexual attraction, and nontraditional aspects of sexual orientation (e.g., asexuality), but also provides insight into the definition and origins of sexual orientation. This article will summarize the current state of research into the biological origins of sexual orientation. After an introduction into the definition of sexual orientation and the biological approach to examining sexual orientation development, the literature on several biological influences are discussed in relation to hormones, genetics, the brain, the body, and the fraternal birth order effect. Future directions in this area of research will conclude the article.

What Is Sexual Orientation?

There are many aspects to an individual's sexual preferences. For example, an individual may prefer individuals of a certain age, ethnicity, body type, or personality, to name a few, for their sexual partner(s). A core aspect of an individual's sexual preferences is, however, their sexual orientation. Although there is no consensus on an exact definition of sexual orientation, generally sexual orientation concerns the sex that an individual is interested in for his/her sexual partner(s). Definitions of sexual orientation can include two components: a psychological component concerning attraction to or fantasies about a certain sex, and a behavioral component concerning the sex of a partner with which an individual actually engages in sexual acts. In recent years, the field has shifted toward an emphasis on the psychological component – specifically sexual attraction – in defining sexual orientation.

Most researchers categorize sexual orientation into three main categories: homosexual, heterosexual, and bisexual, although there is debate among researchers whether sexual orientation is categorical or continuous in nature. 'Homosexual' describes an orientation toward the same sex; 'heterosexual' describes an orientation toward the other sex; and 'bisexual' describes an orientation toward both sexes. Labels of straight (or heterosexual), gay (or homosexual man), and lesbian (or homosexual woman) are often used interchangeably with the homosexual and heterosexual categories. Some recent sexual orientation theorists have suggested a fourth main category of sexual orientation, asexual, the absence of sexual attractions for others, although asexual individuals are much less studied than the three traditionally defined groups – gay/lesbian, straight, and bisexual – mentioned above. It is important to note that although these categorization labels for traditional groups (e.g., gay, lesbian, bisexual) are used in several studies, they are confounded with identity labels (e.g., not all individuals who engage in same-sex behavior identify as gay, lesbian, or bisexual). Thus, this article will use the terms same-sex orientation, both-sex orientation, and other-sex orientation to refer to gay and lesbian individuals, bisexual individuals, and straight individuals, respectively. Various epidemiological studies have indicated that approximately 2–5% of men, and approximately 1–2% of women have a predominant or exclusive orientation toward the same sex, approximately less than 1% of women and men have an orientation toward both sexes (LeVay, 2010), and approximately 1% of the population may be asexual (Bogaert, 2004, 2012).

The Biological Approach

Several approaches have been taken to explain the development of variation in sexual orientation. These include psychoanalytic, learning, and biological approaches, with the two former approaches emphasizing a nurture or environment perspective. Recent researchers have placed an increased emphasis on nature or a biological perspective to investigating the cause of sexual orientation. This emphasis is partly due to the failure of the other approaches in explaining certain aspects of sexual orientation development.

An emphasis on biological influences to sexual orientation development was largely borne out of animal studies that suggested early (i.e., prenatal and neonatal) exposure to testosterone and/or estrogen, which are hormones produced by the gonads, have different effects on the brain, adult sexual behavior, and adult sexual partner preference of males and females in species such as rats, monkeys, and sheep. Current models also include the influence of genes in sex determination and sexual differentiation. For example, the *Sry* gene, which is encoded by the Y chromosome, determines whether the gonads develop into testes or ovaries, and the gonads' hormones, especially testosterone released from the testes, influence the physical

development and neural development of males and females. These organizational effects of gonadal hormones also influence adult sexual behaviors and adult sexual partner preferences. Note, that we are using the word influence to indicate that biology exerts some impact on the development of sexual orientation; however, this does not mean that it directly determines sexual orientation in a fixed manner. With this knowledge about the sexual development of male and female animals, coupled with evidence that some animals engage in same-sex- and/or both-sex-oriented sexual behaviors, researchers studying the origins of sexual orientation development in humans began to explore several biological variables and their relation to sexual orientation development in humans. Some of the key findings of this research are outlined in the following sections.

Hormones

To examine the influence of hormones in sexual orientation development, researchers have examined both circulating hormone levels and prenatal hormone levels. Circulating hormone levels (sometimes called activational or reversible effects) refer to hormones that are currently circulating in adults. Prenatal hormone levels (sometimes called organizational or more permanent effects) refer to hormones present in an individual while he/she is in the womb that influence gonadal and brain development in a fetus. Researchers have generally found that there were no differences in circulating testosterone levels between men with a same-sex orientation and an other-sex orientation. However, some studies have found evidence suggesting that more masculine-identifying women with a same-sex orientation, compared to more feminine-identifying women with a same-sex orientation had higher salivary testosterone levels (Please note that a range of gender expression occurs in individuals. There are clear differences on a group level between men and women in gender expression; however, although average differences exist between men and women, there is also a range of variability within men and within women in gender expression. Likewise, although there is evidence that same-sex-attracted individuals are, on average, more gender nonconforming than other-sex attracted individuals, there is also a wide range of variability within same-sex-attracted and other-sex attracted individuals in gender expression.) As there was not much support for the role of circulating levels of testosterone in sexual orientation development, researchers have focused on the possible influence of prenatal hormones on the organization of the fetal brain with respect to the development of sexual orientation. This research assumes that typical levels of hormones (e.g., testosterone) have been altered in prenatal sexual development (e.g., lowered in male fetuses; raised in female fetuses), and that this atypical exposure to prenatal hormones ultimately predisposes an individual to a same-sex orientation later on in life by affecting areas of the brain (see below) implicated in sexual orientation. Researchers cannot ethically manipulate levels of hormones in an experiment on pregnant women; however, other, more indirect or correlational lines of research have generally provided support for the role of prenatal hormones in human sexual orientation development (e.g., Ellis and Ames, 1987; Hines, 2011; Meyer-Bahlburg, 1984).

One avenue of research is to examine other atypical sexual development. For example, girls and women who have the classical form of congenital adrenal hyperplasia experience an increase in prenatal androgen (e.g., testosterone) levels produced by the adrenal glands. As a result, these girls and women have some degree of masculinized genitals. Studies conducted on the relationship between women with congenital adrenal hyperplasia and sexual orientation have found that women with the most severe forms of this condition have, on average, a reduced other-sex orientation (i.e., have an increased same-sex orientation). Boys and men (i.e., these individuals are born with the XY chromosomes) with androgen insensitivity syndrome and 5-alpha reductase deficiency experience a decreased response to androgens, which results in men with feminized genitals who are, as a result, usually reared as girls. The few studies that have been conducted on these girls suggest that as adults these women are generally interested in men for their partners; however, the results are more complicated in girls with 5-alpha reductase deficiency, as they experience masculinization at puberty and some change to be men as adults (e.g., due to cultural or medical factors). In sum, this research provides some support for the role of androgens in sexual orientation development in both women and men (e.g., Hines et al., 2003; Meyer-Bahlburg et al., 2008; Money et al., 1984).

Another avenue of research is via pregnant women who were prescribed hormones during their pregnancies. In the 1940s–60s, pregnant women were prescribed a synthetic estrogen, diethylstilbestrol (DES), to prevent miscarriage. Thus, these women carried fetuses that were exposed to increased levels of estrogen (which can have masculinizing effects prenatally). Some studies on the offspring of these women indicate that women who were exposed to DES were associated with an increase in same-sex orientation compared to women who were not exposed to DES prenatally. Another study did not find this association, although a less sensitive measure of sexual orientation was used. In men, there was no supported relationship of an increase in same-sex orientation with men who were exposed to DES compared to men who were not exposed to DES. Thus, research provides some support for the role of DES (and by implication estrogen) in sexual orientation development in women only (e.g., Meyer-Bahlburg et al., 1995; Titus-Ernstoff et al., 2003).

The last avenue of research related to hormones discussed in this article concerns childhood behavior. Generally, boys play with male-typical toys (e.g., trucks, cars) and girls play with female-typical toys (e.g., dolls, jewelry). Further, boys engage in more rough-and-tumble play than girls, and the majority of boys and girls have same-sex playmates. Retrospective and prospective studies have found that men and women with same-sex orientations recall more atypical patterns of behavior in their childhood with respect to toy preference, activity preference, and playmate choices. Studies conducted on girls with congenital adrenal hyperplasia have found that these girls show increased levels of childhood atypical behavior as well (e.g., Bailey and Zucker, 1995; Berenbaum and Hines, 1992; Meyer-Bahlburg et al., 2004). This suggests that prenatal androgens may influence the development of childhood playmate choices, toy interests, and activity interests. As a result, because individuals with a same-sex orientation are more likely to show increased levels of childhood atypical

behavior, this provides additional support for the notion that atypical exposure to prenatal androgens is a factor related to sexual orientation development. Thus, these lines of research, and other lines of research not presented here, converge on the idea that hormones are one factor that is related to the development of sexual orientation in humans.

Genetics

Twin studies suggest that there is some degree of genetic influence on sexual orientation. That is, these studies find that monozygotic twins, which share approximately 100% of their genes, have higher concordance rates than dizygotic twins, which share approximately 50% of their genes, for a same-sex orientation; although, the exact concordance rates differ depending on the study. Studies also suggest that there is an increased rate of same-sex orientation among biological siblings. Further, there is some support that the chromosomal region Xq28 on the X chromosome is associated with same-sex orientation in men; however, replication of this finding by an independent group of researchers was not successful and the exact genes in this chromosomal region that are relevant to sexual orientation have not yet been identified as of the date of the writing of this review. Another study has also implicated the X chromosome in sexual orientation development in men. Female cells contain two X chromosomes and one of them is randomly inactivated in early development in each cell. Since this inactivation is random, 50% of the X chromosomes should be maternal in origin and 50% should be paternal in origin (i.e., because women receive one X chromosome from their mother and the other X chromosome from their father). Mothers of gay sons displayed skewing in X chromosome inactivation (i.e., a nonrandom amount of X activation was either paternal or maternal) and this skewing increased with an increase in the number of gay sons. Another study using molecular genetic techniques has provided some support for the role of autosomal genes (i.e., genes not on the sex chromosomes), specifically on chromosomes 7, 8, and 10, in men's sexual orientation development. Although research into the genetics of sexual orientation development is not abundant, the existing research (e.g., Bailey and Pillard, 1991; Bocklandt et al., 2006; Hamer et al., 1993) suggests that there is a genetic component to sexual orientation development, with most studies conducted only in men.

From an evolutionary perspective, same-sex orientations are a paradox: genes that underlie same-sex orientations would not be passed down to future generations because same-sex sexual activity does not result in offspring via sexual reproduction. Yet, same-sex orientations exist (and likely have existed throughout human history) and thus, researchers have proposed theories/hypotheses to explain why genes for a same-sex orientation existed and continue to thrive. One hypothesis based on kin selection argues that genes for a same-sex orientation were indirectly selected for because individuals with a same-sex orientation helped increase the reproductive success of their siblings via aiding in resource accretion or caring for their children. This hypothesis has garnered some support, at least in men, through investigations of the *fa'afafine*, a relatively feminine group of men in Independent Samoa who engage in same-sex behavior. Several studies suggest the *fa'afafine* were more likely to aid their kin than men with an other-sex orientation in Independent Samoa. Another hypothesis that has found support suggests that a same-sex orientation was related to an increased maternal fecundity. There are several other hypotheses; however, these hypotheses have yet to be rigorously tested (see Rahman and Wilson, 2003, for a review). Thus, it is clear that research into the maintenance of genes for a same-sex orientation is underway; however, no clear answer to why such genes are propagated has been established (e.g., Vasey and VanderLaan, 2010).

The Brain

Researchers examining brain structures implicated in sexual orientation development have found some promising results. Aside from being the main organ of behavior (including mediating sexual attraction), the brain is an important area to study with respect to biological influences because the brain is affected by prenatal hormones (among other factors). Current biological models of sexual orientation development include the idea that prenatal hormones affect areas of the brain implicated in sexual orientation development, and these affected areas somehow influence the sexual orientation of an adult individual. Generally, it has been found that the interstitial nuclei of the anterior hypothalamus (INAH), specifically INAH-3, is implicated in sexual orientation. The hypothalamus has many functions, including roles in feeding and drinking, regulation of body temperature, and reproduction/mating. Men with a same-sex orientation, and women with an other-sex orientation had the same cell volume in this area of the hypothalamus; however, the cell volumes in men with a same-sex orientation and women with an other-sex orientation were both smaller compared to men with an other-sex orientation (note: women with a same-sex orientation were not examined). Thus, this area seems to have been organized in a more female-typical direction in men with a same-sex orientation. This finding was partially replicated by an independent set of researchers. Homologous sites, such as the sexually dimorphic nucleus of the preoptic area, have been implicated in mating behavior in rodents, and other mammals (e.g., LeVay, 1991).

Other brain areas have been implicated in sexual orientation. For example, the suprachiasmatic nucleus was found to be larger in men with a same-sex orientation than men with an other-sex orientation by one set of researchers; however, the finding is difficult to interpret since the suprachiasmatic nucleus is not known to be involved in anything sexual, but is involved in regulation of circadian rhythms. A study also suggested that the anterior commissure, which is a set of smaller fibers that connect the two cerebral hemispheres of the brain, was larger in men with a same-sex orientation than men with an other-sex orientation. Thus, this area also appeared to be slightly feminized in men with a same-sex orientation, as previous studies indicated that women with an other-sex orientation have a larger anterior commissure than men with an other-sex orientation. Another study indicated that the isthmus, a section of the corpus callosum that connects parts of the parietal lobe and temporal lobe in the left and right

hemispheres, respectively, was larger in right-handed men with a same-sex orientation compared to right-handed men with an other-sex orientation. The isthmus has been shown to be larger in nonright-handed individuals than right-handed individuals (*see* Section The Body). Further, one study demonstrated that men with an other-sex orientation have a right cerebral hemisphere that was larger than the left cerebral hemisphere, while women with an other-sex orientation have left and right cerebral hemispheres that were the same size. Men with a same-sex orientation had the same size left and right cerebral hemispheres, similar to women with an other-sex orientation, and women with a same-sex orientation had a right cerebral hemisphere that was slightly larger than the left cerebral hemisphere, which slightly aligned with the findings in men with an other-sex orientation. Other studies have implicated the perirhinal cortex (involved in olfaction, spatial processing, and memory) in women with same-sex orientation, and the amygdala in men and women with same-sex orientation, with shifts in the sex-atypical way. Thus, it is clear that there are a number of important brain areas associated with sexual orientation, although much of this work has only been conducted in men, is very recent, and requires replication (see Bao and Swaab, 2011; LeVay, 2010, for reviews). Note that although the assumption in this research is that the causal direction is such that the brain influences sexual orientation, the direction of causality is still unclear (i.e., it is possible that sexual orientation may influence the structure of the brain or a third variable influences both brain structure and sexual orientation).

The Body

Some sexual orientation researchers have examined sex dimorphic physical characteristics that are influenced by prenatal hormones, and then examined if men and women with a same-sex orientation differ from men and women with an other-sex orientation on these characteristics. Specifically, these researchers aim to determine whether these characteristics are shifted in the female-like way in men with a same-sex orientation and male-like way in women with a same-sex orientation, compared to men and women with an other-sex orientation, respectively. If physical development in men and women with a same-sex orientation is shifted in this way, then it suggests that prenatal hormones are, along with affecting these physical development characteristics, altering structures of the brain relevant to sexual orientation. This research strategy underlies a number of research programs on sexual orientation development, including 2D:4D finger ratios, handedness, otoacoustic emissions, and height.

Women have a higher ratio of the length of the second digit to the length of the fourth digit (i.e., 2D:4D finger ratio) than men. Some studies have found that prenatal androgen exposure (or androgen/estrogen exposure) underlies this sex difference. With respect to the association of 2D:4D finger ratios and sexual orientation, findings have been mixed. Some studies reported that men with a same-sex orientation had a more female-typical ratio, while others reported no difference or a more male-typical ratio; other studies reported that the ratio was more male-typical in only the right hand. A recent meta-analysis concluded that women with a same-sex orientation had a more male-typical 2D:4D finger ratio, but there was no relationship between sexual orientation and 2D:4D finger ratio and sexual orientation in men (Grimbos et al., 2010).

Boys and men are more likely to be nonright-handed than girls and women, and it has been argued that handedness is determined prenatally, including a possible role for prenatal hormones. Several studies have been conducted on the relationship between handedness and sexual orientation with mixed results. A meta-analysis of 20 such studies concluded that men with a same-sex orientation are 34% more likely than men with an other-sex orientation to be nonright-handed, and women with a same-sex orientation are 91% more likely than women with an other-sex orientation to be nonright-handed (Lalumiere et al., 2000).

Otoacoustic emissions are sounds produced in the cochlea (a structure inside the inner ear) that can be recorded from the outer ear. They can be spontaneously produced (i.e., spontaneous otoacoustic emissions (SOAEs)) or produced after a sound is presented to the ear (i.e., click-evoked otoacoustic emissions (CEOAEs)). Generally, the right ear has more SOAEs than the left ear and women have more SOAEs than men. CEOAEs are stronger in the right ear than in the left ear and women have stronger CEOAEs than men. These sex differences exist in newborns and thus, the sex difference is assumed to be determined prenatally by androgens. Studies have found that the number of SOAEs was decreased and the strength of CEOAEs was weakened in women with a same-sex orientation, similar to the patterns found in men with an other-sex orientation; however, there was no relationship between sexual orientation in men and the number of SOAEs and strength of CEOAEs. Thus, the otoacoustic emission research provides evidence of shifts in the male-typical way in women with a same-sex orientation in terms of SOAEs and CEOAEs; however, shifts in the female-typical way were not found in men with a same-sex orientation (McFadden and Champlin, 2000).

Men are generally taller than women and prenatal hormones have been partially found to underlie this sex difference. The majority of studies conducted on the relationship between height and sexual orientation have found that men with a same-sex orientation were shorter, on average, than men with an other-sex orientation. The relationship between height and sexual orientation in women is less consistent, with the majority of studies not finding a difference in height between women with a same-sex orientation and women with an other-sex orientation (e.g., Bogaert and Blanchard, 1996; Bogaert, 2010).

Overall, the research programs investigating several physical markers of prenatal hormone exposure have found some support for a relationship between 2D:4D finger ratios, handedness, otoacoustic emissions, and sexual orientation in women, as well as support for a relationship between handedness, height, and sexual orientation in men. Indirectly (i.e., because these studies are correlational), these studies add support to the idea that prenatal hormones are a factor in sexual orientation development.

The Fraternal Birth Order Effect

It has been consistently shown in various samples and by independent researchers that men with a same-sex orientation

tend to have an increased number of older brothers than men with an other-sex orientation (i.e., a later fraternal birth order). It has been estimated that each additional older brother increases the chance of same-sex orientation by 33%. This effect has been termed the fraternal birth order effect because the number of older sisters is not associated with sexual orientation in men, and the number of older sisters and older brothers is not associated with sexual orientation in women. Studies have ruled out potential confounding variables to explain the fraternal birth order effect, such as year of birth, age, socioeconomic status, sibship size, and parental age. Further, the fraternal birth order effect has been demonstrated even if biological older brothers were reared in a different household, and independent of the presence of adopted older brothers or older stepbrothers (Blanchard and Bogaert, 1996; Bogaert and Skorska, 2011).

An immunological explanation, termed the maternal immune hypothesis, has been proposed as an explanation for the fraternal birth order effect. Although there is no direct empirical support (yet) for the maternal immune hypothesis, there has been no feasible alternative explanation of the fraternal birth order effect to date. Specifically, the maternal immune hypothesis postulates that the mother's immune system is continuously immunized to male-specific proteins (associated with the Y chromosome, which a mother does not have) with each successive male fetus. The increasing concentration of antibodies the mother develops after each male fetus cross the blood–brain barrier to affect specific areas in the brain associated with sexual orientation development, which would then influence the sexual orientation of the man as an adult. Several lines of research indicate that transfer of material occurs from the fetus to its mother, male-specific substances cause immune responses in women, the relevant male-specific substances play a role in sexual differentiation of the brain (independent of prenatal hormones), and a maternal immune response to male-specific substances affects fetal brain development. These lines of research increase the plausibility of the maternal immune hypothesis in explaining the fraternal birth order effect, and more direct empirical investigations testing this hypothesis are currently underway.

Future Directions

The study of the origins of the complex trait of sexual orientation has come a long way since 1973. Through the efforts of numerous researchers, it is clear that there is increasing evidence that biology influences sexual orientation development in humans (note, again that an 'influence' does not mean that biology determines sexual orientation in a fixed manner). However, the field of sexual orientation research is still quite young and there are several questions that require answering in the future. For example, there is less sexual orientation research in women than in men (e.g., the genetics and brain research has been mostly done in men). To understand how sexual orientation develops requires a good understanding of the developmental processes in both men and women. There is also a lack of studies of individuals who are attracted to both sexes and those attracted to neither sex (i.e., asexual individuals). The field would benefit from conducting more research into these groups of individuals, as they will provide important new insights into sexual orientation development, broadly defined. As well, the findings in studies that have been conducted thus far often require replication in different samples to ensure the effects are reliable and generalizable to the wider population. For example, the majority of studies are on middle-class caucasian Western individuals, with several studies using small samples sizes. Further, many of the studies that have been conducted thus far need to be extended to rule out alternative explanations, as they often only provide indirect support for biological mechanisms. Last, the biological research into sexual orientation development could integrate with research and theory on the environmental origins of sexual orientation to provide a complete picture of how a complex trait such as sexual orientation develops. For example, women's sexuality has been argued to be more flexible in sexuality and sexual orientation compared to men's sexuality (e.g., Baumeister, 2000). With several questions left to answer and numerous studies to be conducted, the future of research into the biological influences on sexual orientation development (and sexual orientation development more generally) looks promising.

Sexual Orientation: Genetic Aspects

Khytam Dawood, Pennsylvania State University, University Park, PA, USA

Abstract

This article will provide an overview of the evidence on the genetics of sexual orientation, including family and twin studies and molecular genetics findings to date. Familial aggregation of sexual orientation has been reported in several family studies of both male and female homosexuality, although the genetic and environmental influences on this familial clustering have not been clearly defined by the largest twin studies published thus far. Recent molecular genetic studies will also be reviewed, including the two main strategies that have been used to date – linkage and association analyses. The implications of recent advances in molecular genetic studies will also be discussed.

Introduction

Sexual orientation describes what is erotically attractive to an individual and is usually consistent with sexual identity that refers to an individual's labeling of self as heterosexual, homosexual, or bisexual; both are typically not consolidated until adolescence or later. Older studies tended to define sexual orientation behaviorally, whereas most current researchers define sexual orientation psychologically. Because sexual attraction and fantasy are less likely than behavior to be constrained by societal pressures, psychological sexual orientation is thought to be a more stable and fundamental trait. A psychological definition of sexual orientation tends to produce lower prevalence figures (Dawood et al., 2009; Laumann et al., 1994) compared to a behavioral one (Chandra et al., 2011), and is used in most of the studies demonstrating familiality and heritability.

This article will provide an overview of the evidence on the genetics of sexual orientation, including family and twin studies and molecular genetics findings to date. Male and female sexual orientation appear to be distributed differently in the general population. For men, sexual orientation typically appears to be bimodally distributed, with most men clustered at the heterosexual end of a continuum, many fewer at the homosexual end, and the fewest men in the bisexual middle (Rieger et al., 2005; Bailey et al., 2000). Female sexual orientation tends to taper gradually from exclusively heterosexual to exclusively homosexual (Bailey et al., 2000). The bulk of the available evidence suggests moderate heritability for male and female sexual orientation (Dawood and Bailey, 2000; Dawood et al., 2009). Female sexual orientation has been studied less extensively, but current studies are consistent with a genetic contribution for women as well (Pattatucci and Hamer, 1995; Kirk et al., 2000). Familial aggregation of sexual orientation has been reported in several family studies of both male and female homosexuality (Dawood and Bailey, 2000), although the genetic and environmental influences on this familial clustering have not been clearly defined by the largest twin studies published thus far, which have produced contradictory results. Recent molecular genetic studies will also be reviewed, including the two main strategies that have been used to date – linkage and association analyses. The implications of recent advances in molecular genetic studies will also be discussed.

Behavior Genetic Studies

Traditionally, behavior genetic research has proceeded in three main stages. *Family studies* are initially conducted to determine whether a trait or characteristic (often called a phenotype) runs in families by comparing rates in families of probands (i.e., individuals possessing the trait) versus families of controls (that typically represent the base rate in the general population). If there is a heritable genetic contribution to a trait, one expects to find familial aggregation. However, the mere demonstration of clustering of a trait in families does not prove a genetic influence, because some traits run in families for environmental reasons.

Twin studies are conducted in order to separate genetic from familial environmental effects by comparing the similarity of monozygotic (MZ, also called identical) and same-sex dizygotic (DZ, also called fraternal) twins who have been reared together. MZ twins share all their genes in common, whereas DZ twins share 50% of their segregating genes on average, just like any other pair of full siblings. Since both twins share the same pregnancy, it is assumed that they experience essentially the same prenatal environment. Because both twins have also been reared together, their postnatal environment is assumed to be approximately equal. Thus, if MZ twins are more similar (i.e., concordant) for a trait than DZ twins, this is assumed to reflect their greater genetic similarity and is evidence that genetic factors influence the phenotype. Twin studies allow one to estimate heritability, defined as the proportion of the variance in expression of the trait due to all genetic influence(s) combined. Results from twin studies support a significant environmental contribution to most behavioral traits since MZ twins are not 100% concordant.

Adoption studies are a further method used to separate the effects of genes from the environment. Adoption produces family members who share family environment but are not genetically related, and vice versa. Thus, this method allows one to estimate the contribution of family environment to family resemblance. Studies on both male and female sexual orientation exist from all three research methodologies.

Family Studies

In the past three decades, several contemporary family genetic studies have been conducted on sexual orientation in men and women. All available studies have focused on the rate of homosexuality in siblings rather than in other first-degree relatives (e.g., parents or offspring), due to the decreased reproduction of homosexual individuals.

Both male and female homosexuality appear to run in families (Bailey and Pillard, 1991; Bailey and Benishay, 1993; Bailey et al., 1993; Bailey and Bell, 1993; Pattatucci and Hamer, 1995; Bailey et al., 1999; Schwartz et al., 2010). The rate of homosexuality among brothers of homosexual males has consistently been around 9% (Bailey and Pillard, 1991). These results have exceeded those for heterosexual controls, as well as the prevalence estimates from recent large-scale epidemiological surveys, suggesting that male homosexuality is familial. Homosexual women also appear to have more homosexual sisters than do heterosexual controls, though the familiality estimates have varied more widely for women. There is a trend for male homosexual probands to have more homosexual brothers than lesbian sisters and for the opposite pattern to be seen for lesbian probands, suggesting that at least some of the familial factors influencing male homosexuality differ from those influencing female homosexuality. However, the degree of cofamiliality (reflecting common familial influences) of male and female homosexuality remains inconclusive (Dawood et al., 2000).

Twin Studies

Several large-scale twin studies have been conducted in the past two decades, and they have been generally consistent in detecting moderate to large heritabilities for both male and female sexual orientation. However, there have been methodological limitations, in particular, several of the large twin studies of sexual orientation recruited probands via advertisements in gay or lesbian publications. Such sampling is likely to result in volunteer bias that affects twin concordances and heritability analyses, though in most scenarios this would be more likely to lead to a false-negative study. More recently, investigators have reported results from population-based twin studies, and the discussion here will focus on these large-scale findings.

Bailey et al. (2000) systematically recruited twins from a twin registry and reported lower twin concordances for homosexuality than in prior studies, although their findings were also consistent with moderate to large heritabilities for male and female sexual orientation. A further analysis of these data using multivariate structural equation modeling estimated heritability of the latent variable of male homosexuality around 30% and for female homosexuality around 50% (Kirk et al., 2000).

Kendler et al. (2000) recruited 756 twin and nontwin sibling pairs from a US national probability sample and found that 32% of MZ twins were concordant for homosexual orientation versus 13% of DZ same-sex twins. The concordance rates for MZ twins were lower than those reported in previous studies that recruited via advertisements in gay publications suggesting that twin pairs concordant for sexual orientation may be more likely to respond to such ads than are twin pairs discordant for sexual orientation. It is also worth noting that unlike previous studies in this area, this study assessed sexual orientation by a single item on a self-report questionnaire.

Bailey et al. (2000) recruited male and female twin pairs systematically from the Australian Twin Registry and assessed their sexual orientation as well as two related traits: childhood gender nonconformity and continuous gender identity. Twin concordances for homosexual orientation were lower than in prior studies with 20% of male MZ twins concordant versus 0% of DZ twins, and 24% of female MZ twins versus 10.5% of DZ twins. Univariate analyses showed that familial factors were important for all traits, but were less successful in distinguishing genetic from shared environmental influences. Multivariate analyses suggested that the causal architecture differed between men and women, and, for women, provided significant evidence for the importance of genetic factors to the traits' covariation.

Most recently, two large-scale twin studies examining sexual orientation in men and women were reported with similar results. Alanko et al. (2010) conducted a study of genetic effects of childhood gender atypical behavior and adult sexual orientation in a population-based sample of 3261 Finnish twins. Quantitative genetic analyses demonstrated that variation in both traits was partly due to genetics, with the rest explained by nonshared environmental effects. Bivariate analyses implicated substantial common genetic and modest common nonshared environmental correlations underlying the co-occurrence of childhood gender atypical behavior and adult sexual orientation (Alanko et al., 2010).

Langstrom et al. (2010) conducted the largest twin study of sexual orientation to date. The authors used data from a population-based survey of all adult twins in Sweden to estimate the influence of genetic and environmental effects on same-sex sexual behavior. A sample of 3826 MZ and DZ same-sex twin pairs were used in the study, which found familial clustering of same-sex sexual behavior in both men and women. The results indicated that same-sex behavior is influenced by both heritable and unique or nonshared environmental variables, with heritability estimates of 0.34–0.39 for men and 0.18–0.19 for women. Further, the authors note that hereditary effects appeared weaker in women, though these were not statistically significant (Langstrom et al., 2010). The study is also noteworthy for achieving greater statistical power and higher response rates than previous such research, providing the most unbiased estimates to date of genetic and nongenetic contributions to same-sex behavior.

Molecular Genetic Studies

Once a solid foundation of support for significant genetic influence on a trait has been built by means of behavior genetics (family, twin, and adoption studies), as has been the case for sexual orientation especially with males, molecular genetic studies are a next logical step. The two primary varieties of these studies are association and linkage designs.

Association studies are based on linkage disequilibrium. This means that a gene variant influencing a trait was initially

associated with specific alleles of nearby polymorphic loci. As generations (and the meioses that produce sperms and eggs) pass, the trait-influencing gene and marker allele may remain statistically associated because their proximity reduces the number of recombinations or crossing-over events that occur between them. An advantage of association tests is that the chromosomal region examined is usually much smaller than the region examined by testing for linkage in families. Association is often more powerful than linkage in that a valid association may be detected in a sample when linkage is not detectable, even when the gene is playing only a modest role. Most association studies in the past were the population-based type where the allele frequencies of a group of unrelated cases were compared against those of a group of unrelated controls, and this is the only type of association study that has been carried out on male sexual orientation. A potential pitfall of population-based case–control studies is that, although some populations appear homogeneous to superficial examination, they are in reality composed of different ancestral human groups, each one potentially with a different allele distribution at the studied loci. If one or more such groups are represented in a largely different proportion in one of the samples of an association data set (i.e., either in the controls or in the cases), false-negative or false-positive association findings may easily arise due to methodological artifact.

Linkage analysis exploits the key biological phenomenon during generation of sperm and eggs of meiotic recombination, or crossing over, during which both the maternally and paternally derived chromosomes lie in close proximity and undergo exchange of genetic material between the homologous chromosomes, e.g., between a paternally derived chromosome and its maternally derived counterpart. The chance of crossing over between two loci (locations on a chromosome) is referred to as the recombination fraction. Genes and other genetic markers (DNA sequence variations known as polymorphisms) that are close together are less likely to be separated by this process than are those that are farther apart. Therefore, they are usually inherited together by the progeny cells, and are considered genetically linked. Due largely to the complexity of the genetic contributions to male sexual orientation and uncertainty regarding key parameters (mode of inheritance, number of relevant genes, etc.), the type of linkage analyses preferred are nonparametric allele-sharing methods, and more specifically, the affected sibling pair (ASP) method. ASP designs measure the frequency with which a genetic marker allele (or variant) is inherited from a particular parent (referred to as IBD, meaning identical by descent) in a pair of siblings both manifesting the trait. The presence of a trait-influencing gene is revealed when the IBD allele sharing between affected siblings exceeds the expected 50%.

Association Studies

Two association studies have been performed to date for male homosexuality. Macke et al. (1993) used a population based case–control method to examine DNA sequence variation in the androgen receptor gene, reasoning that some variants may affect sexual differentiation of the brain. This study employed a sample of 197 homosexual males and 213 unselected (with respect to sexual orientation) male controls with variants of the androgen receptor gene located on the X chromosome (but not at Xq28), and found no significant differences in the distributions of mutations in homosexual and heterosexual men (i.e., no evidence for association). This gene was selected for examination partly due to its location on the X chromosome since there is some evidence for excess maternal transmission of male homosexuality, which would be consistent with X-linked transmission. However, using linkage analysis, the authors showed that sibling pairs concordant for homosexuality were no more likely than chance to share the same androgen receptor allele.

Another reason the androgen receptor was chosen for examination was not due to its position, but rather due to its function, which is to transduce messages from androgens ('male' hormones) to the nucleus of the cell, thus affecting other genes responsive to androgens. In addition, androgens masculinize the brain and behavior, and homosexual individuals are sex-atypical on some behavioral and neural characteristics (Rahman, 2005). In general, many different 'candidate' genes may be nominated for examination by means of association testing, but the strength of their candidacy is often in question (relative to any other gene expressed at some point in the brain, which most are). For example, studies in animal models where gene variation may be introduced and the effects systematically examined may suggest genes to examine in humans, but there is an unresolved question regarding the validity of extrapolating complex behaviors from species sometimes as different from humans as fruit flies.

Dupree et al. (2004) conducted an association study of male sexual orientation to investigate whether differences in the gene encoding the aromatase enzyme influence sexual orientation in men. Aromatase cytochrome P450 (CYP19) is necessary for the conversion of androgens to estrogens, and plays an important role in the sexual differentiation of the brain in rodents. This study found no differences between heterosexual and homosexual men in the expression of aromatase mRNA by microarray analysis, suggesting that variation in this gene is not likely to be a major factor in the development of individual differences in male sexual orientation (Dupree et al., 2004).

Linkage Studies

The findings to date from behavior and molecular genetic studies predict that the genetics of male homosexuality will not be simple, and this prediction is consistent with the results of linkage research thus far. Several linkage analyses of male homosexuality to the X chromosome have previously been reported (Hamer et al., 1993; Hu et al., 1995; Sanders et al., 1998; Rice et al., 1999). These studies have been largely based on the assumption that oligogenic transmission (a 'few' genes contribute) was most likely, and therefore relied on the ASP method of linkage analysis. While the Xq28 chromosomal region in Hamer et al.'s (1993) study showed a significant linkage signal, with supporting data in a second data set from the same group in a follow-up study (Hu et al., 1995), it is still indeterminate (as in many complex traits) whether this finding represents a true positive. An independent group (Sanders et al., 1998) found inconclusive evidence of linkage to Xq28 in 1998, and a third group (Rice et al., 1999) found no support

for linkage to Xq28 in 1999. Combining all four linkage studies, with respective affected sibling pair (ASP) sample sizes of 40 (1993), 33 (1995), 54 (1998), and 52 (1999), yields a 'multiple scan probability' (MSP) of 0.000 03, which is a suggestive *p*-value when considering all of the chromosomes, i.e., the entire genome (Sanders and Dawood, 2003). The replication MSP (excluding the original positive report from 1993) of 0.07 is at the level of a 'trend' and thus not quite statistically significant. This pattern of results is one that has been predicted for complex traits with oligogenic inheritance on the basis of simulation studies: stochastic variation in the degree of cosegregation of any one locus with a trait, which produces variation in the magnitude of linkage findings across samples. Of course, the sample size of the individual linkage studies should be considered a major factor.

Hamer et al.'s (1993) original report consisted of two major analyses: a pedigree study and a linkage study. First, they examined family pedigrees in a 'randomly ascertained' sample of homosexual probands and found that the probands had a high rate of homosexual brothers, 13.5%, relative to the base rate of homosexuality in the general population. Furthermore, their pedigrees showed an excess of homosexual uncles and male first cousins on the maternal side compared to the paternal side, though the difference was not significant. This excess was more pronounced in a subsequent analysis of an additional sample of 38 families with two homosexual brothers. If there are genes for male sexual orientation, then these families should be especially rich with them. The probands' maternal uncles and cousins (through maternal aunts; no homosexual cousins were sons of maternal uncles) had rates of male homosexuality of 10.3% and 12.9%, respectively, compared to rates of 1.5% and 3.1% for paternal uncles and cousins. This pattern of results is precisely what one would expect if an X-linked gene influenced male sexual orientation. In X-linked inheritance, males with the trait inherited the gene from their mothers, and hence have more maternal than paternal relatives with the trait.

Because of the suggestion of X linkage, Hamer et al. (1993) then searched the X chromosome using linkage analysis. Specifically, they looked at the pairs of homosexual brothers without evidence of paternal transmission (e.g., they excluded a few cases in which the father may have been homosexual; the pairs analyzed in the linkage study included all eligible pairs analyzed in both pedigree studies). They examined 22 genetic markers distributed across the X chromosome, in order to see if brothers concordant for homosexuality were also concordant for the markers. For chromosomal region Xq28 at the tip of the long arm of the X chromosome, 33 of 40 pairs of homosexual brothers shared all the markers. This was statistically different from the expected rate (20 of 40), suggesting that a gene influencing male sexual orientation lies within that chromosomal region.

To date, at least four major replication attempts have been reported, including Hu et al. (1995) from Hamer's own research group. Rice et al. (1999) obtained pedigree information from 182 families with at least two homosexual brothers. They failed to find a significant excess of homosexual maternal uncles or cousins. In a subset of 41 sibling pairs, they also failed to replicate the finding of linkage to Xq28. Unlike Hamer et al. (1993), however, Rice et al. did not exclude brother pairs with strong evidence of paternal transmission, and it is unclear how many of their subjects would have met Hamer et al.'s (1993) inclusion criteria.

In contrast, Hu et al. (1995) from Hamer's lab reported a successful replication. In this second study, Hu et al. included data from heterosexual brothers as well as homosexual brothers, and found that brothers' similarity for sexual orientation was statistically related to the sharing of Xq28 markers. That is, not only did homosexual brothers tend to share the markers, but also gay–straight pairs tended not to share the markers. The magnitude of the genetic effect was smaller in Hamer's second study, however, and the result was barely statistically significant.

Additional Molecular Genetic Studies

A host of recent studies (Mustanski et al., 2005; Bocklandt et al., 2006; Ramagopalan et al., 2010) has provided additional evidence supporting a heritable component to male and female sexual orientation, and these molecular studies are discussed in further detail below.

Mustanski et al. (2005) conducted the first full genome-wide linkage scan of sexual orientation in men by genotyping 456 individuals from 146 families with two or more homosexual brothers with 403 microsatellite markers at 10-cM intervals. They failed to replicate linkage to Xq28 in the full sample; however, they reported three new regions that approached the criteria for near significance (7q36) and for suggestive linkage (8p12 and 10q26). These chromosomal regions may be used in future replication studies with new samples and denser linkage maps.

Ramagopalan et al. (2010) reported results from a second genome-wide linkage scan of male sexual orientation in an attempt to replicate the above findings. In lieu of using microsatellite assays, the researchers conducted single-nucleotide polymorphism-based scans for linkage on the basis that these provide significantly greater genomic coverage and information content (Ramagopalan et al., 2010). The study used a Canadian cohort of 55 families with two or more homosexual brothers and reported no evidence for linkage at or around 7q32 as found by Mustanski et al. (2005) and no other genome-wide significant logorithm of odds (LOD) scores. The authors concluded that genes involved in male homosexuality probably exert more modest effects than can be detected by linkage analysis.

The most recent linkage study of male sexual orientation is also by far the largest study of its kind to date. Sanders et al. (submitted for publication) conducted a genome-wide linkage scan using DNA samples collected from 409 independent pairs of homosexual brothers (908 analyzed individuals in 384 families). It is noteworthy that all previous genetic linkage studies of male sexual orientation were conducted on smaller sample sets. Two regions of linkage were identified – the pericentromeric region on chromosome 8, and Xq28, which was implicated in prior research (Hamer et al., 1993; Hu et al., 1995). These new results appear to support the existence of genes on chromosome 8 and the X chromosome that influence the development of male sexual orientation (Sanders et al., submitted for publication).

Using a different approach that also implicates the role of the X chromosome, Bocklandt et al. (2006) measured X chromosome inactivation in a sample of 97 mothers of homosexual men and 103 age-matched control women without homosexual sons. They reported extreme skewing of X inactivation was significantly higher in mothers of homosexual men (13%) compared to controls (4%), and increased in mothers with two or more homosexual sons (23%). These findings support a role for the X chromosome in regulating sexual orientation in some homosexual men (Bocklandt et al., 2006), although it is unclear whether these unusual X-inactivation patterns influence the development of sexual orientation in sons via a direct mechanism such as the fraternal birth order effect (Blanchard, 1997), or whether it is the indirect result of a different mechanism. These results have yet to be replicated.

Higher Fecundity of Female Maternal Relatives of Homosexual Men

Camperio-Ciani et al. (2004) were the first to report a significant increase in the fecundity of female maternal relatives of homosexual men in a family study that also replicated prior research showing that homosexual men have more maternal homosexual relatives (Hamer et al., 1993), and that homosexual men tend to be later born with more older brothers than older sisters (Blanchard, 1997, 2004, 2008). This finding supports an X chromosomal genetic factor that is associated with homosexuality in men and promotes fecundity in female carriers. Since then, several studies have replicated this finding (Iemmola and Camperio-Ciani, 2009; Rahman et al., 2008; Schwartz et al., 2010; VanderLaan and Vasey, 2011; Rieger et al., 2012; Camperio-Ciani and Pellizzari, 2012), as well as a similar pattern in female maternal relatives of bisexual men (Camperio-Ciani et al., 2009; but see Blanchard, 2012). Evidence that genes predisposing to homosexuality may simultaneously increase the reproductive success of heterosexual relatives would also resolve the evolutionary conundrum of the genetic stability of male homosexuality in the general population (Zietsch et al., 2008).

The Fraternal Birth Order Effect

Several excellent reviews of biological research on human sexual orientation have been published within the past decade (Mustanski et al., 2002; Rahman, 2005), which can provide more comprehensive reviews of neuroendocrine and neurodevelopmental theories of sexual orientation. However, perhaps the most replicated finding in sexual orientation research is the fraternal birth order effect in homosexual men (Blanchard, 2008) whereby homosexual men have a greater number of older brothers than heterosexual men do, in diverse community and population-level samples. The estimated odds of being homosexual increase by approximately 33% (from the base rate in the general population) with each older brother, and statistical modeling using epidemiological procedures suggest that one in seven homosexual men owe their sexual orientation to the fraternal birth order effect (Cantor et al., 2002). While purely genetic factors could not explain this effect, recent evidence suggests that the effect is related to prenatal events (Blanchard, 2004; Bogaert, 2006). Currently, a maternal immune response to male-specific, Y-linked antigens is the most plausible explanation for this effect (Bogaert and Skorska, 2011), which becomes stronger with each male pregnancy. However, empirical studies supporting this hypothesis have yet to be conducted.

Directions for Future Research

During the past two decades, a growing body of evidence has accumulated suggesting that familial and genetic factors affect both male and female sexual orientation. The genetic evidence is substantially stronger for male than for female sexual orientation, and multiple genes are likely to influence the development of sexual orientation.

Although ongoing studies investigating genetic sources of variation in sexual orientation will contribute a critical aspect for understanding the origins and development of sexual orientation, perhaps the most interesting topic for future research in this area lies in studying nonshared environmental sources of variation, and the epigenetic relationship between environmental and genetic factors.

The study of discordant MZ twins, who are genetically identical, can be particularly important since nonshared environmental factors are responsible for MZ twins discordant for sexual orientation. For example, future molecular genetic studies could examine epigenetic modifications of DNA between twins using a genome-wide screen of differentially methylated regions to identify potential discrete differences between homosexual and heterosexual MZ twins.

At this stage, few conclusions can be drawn with certainty regarding genetic and environmental determinants of sexual orientation. Important methodological research innovations hold the most potential for furthering our knowledge on the origins and development of human sexual orientation. Future research should also attempt to integrate different biological approaches in order to provide valuable information about the specific pathways by which genes exert their influence on sexual orientation and its correlates.

Sexual Orientation: Historical and Social Construction

Jeffrey Weeks, London South Bank University, London, UK

Abstract

Sexual orientation suggests an essential sexual nature. The task of historical or social constructionist approaches is to suggest that it is this belief that needs investigation. Such approaches seek to do two broad things: to understand the emergence of sexual categorizations (such as the 'homosexual' or the 'heterosexual' in Western cultures since the nineteenth century) within their specific historical and cultural contexts and to interpret the sexual meanings, both subjective and social, which allows people to identify with, or reject, these categorizations. It is thus largely preoccupied not with what *causes* individual desires or orientations, but with how specific definitions develop within their historical contexts, and the effects these definitions have on individual self-identifications and collective meanings.

Sexual orientation is a much used but fundamentally ambiguous concept. Although the concept had its origins in debates over the meaning of the sexual instincts in sexological theories of the nineteenth century, it came into widespread use in discussions of sexuality in the 1970s, largely as a synonym for homosexual desire and object choice, less frequently for heterosexual patterns, although in theory, it encompasses all sexual tendencies. Sexual orientation, as a concept, suggests an essential sexual nature, deeply rooted in the human personality, shaping sexual desire, behavior, and identity. The challenge that historical or social constructionist approaches have taken up is to suggest that these essentialist assumptions are what actually need investigation. Why is contemporary culture so preoccupied with discovering a fixed, true sexual nature in each individual? A more historically grounded analysis seeks to do two broad things: to understand the emergence of sexual categorizations (such as 'the homosexual' or 'the heterosexual' in Western cultures since the nineteenth century) within their specific historical and cultural contexts and to interpret the sexual meanings, both subjective and social, which allow people to identify with, or reject, these categorizations. Such analysis is thus largely preoccupied not with what *causes* individual desires or orientations, but with how specific definitions *develop* within their historic contexts, and the effects these definitions have on individual self-identifications and collective meanings.

The Rise of Historical Approaches to Sexuality

Historical and social explanations of sexual desire and behavior are usually counterposed to what are called essentialist explanations. Essentialist assumptions are central to traditional ways of thinking about sexuality, both in common sense knowledge and in theory. Until relatively recently, most writers on sexuality saw it as an irresistible natural energy, rooted in biology, and barely held in check by a thin crust of civilization. This was foundational for the pioneers of sexology from the late nineteenth century. Essentialist views of sexuality have been inextricably linked with assumptions about gender. The genital and reproductive distinctions between biological men and biological women have been read not only as necessary but also as sufficient explanation for different sexual needs and desires. They appear as the most basic distinctions between peoples. It followed that when speculations began about the origins of homosexuality, it was taken for granted that they lay in a perversion or inversion of the biological direction to the opposite sex. So the male homosexual was seen as having a female soul in a male body, or in the case of lesbianism a male soul in a female body. Later theories sought explanations in hormonal, genetic, or psychological differences, but all tended to assume a problem in the natural direction of object choice. Heterosexuality was assumed to be the normal given state of the human individual, from which everything else was an unfortunate distortion or deviation (Weeks, 2009). The implications of such imagery are deeply conservative, assuming the intractability to change of social institutions and the inevitability of certain givens, such as male/female or heterosexual/homosexual differences. Social explanations, on the contrary, have sought to question and problematize these naturalistic assumptions, and to demonstrate that what was made in history can be changed in history.

The classical starting point for social constructionist approaches is widely seen as an essay on 'The Homosexual Role' by the British sociologist, Mary McIntosh (1968). Its influence can be traced in a range of historical studies from the mid-1970s (Weeks, 1977; Trumbach, 1977), and it has been frequently anthologized (for example, Stein, 1992). What is important about the work is that it asked what was at the time a new question: not, as had been traditional in the *sexological* tradition from the late nineteenth century, what are the *causes* of homosexuality, but rather, why are we so concerned with seeing homosexuality as a condition that has causes? And in tackling that new question, McIntosh proposed an approach which opened up a new research agenda: through seeing homosexuals 'as a social category, rather than a medical or psychiatric one.' Only in this way, she suggests, can the right questions be asked, and new answers be proposed. Using Kinsey (Kinsey et al., 1948), McIntosh makes a critical distinction between homosexual behavior and 'the homosexual role.' Homosexual behavior is widespread; but distinctive roles have developed only in some cultures, and do not necessarily encompass all forms of homosexual activity. The creation of a specialized, despised, and punished role or category of homosexual, such as that which developed in Britain from the early eighteenth century, was designed, she argued, to

keep the bulk of society pure in rather the same way that the similar treatment of some kinds of criminal keeps the rest of society law abiding. McIntosh drew on a variety of intellectual sources, from structural functionalism to dramaturgical approaches, but clearly central to her argument was a form of labeling theory. The creation of the homosexual role was a form of social control designed to minoritize the experience, and protect and sustain social order and traditional sexual patterns. In other words, homosexual identifications were less the result of some inbuilt drive than of social constraints and possibilities.

If McIntosh put on the agenda the process of social categorization, another related but distinctive approach that shaped social constructionism came from the work of John Gagnon and William Simon, summarized in their book *Sexual Conduct: The Social Sources of Human Sexuality* (1974). Drawing again on the work of Kinsey, and symbolic interactionist traditions, they argued that, contra to the teachings of sexology, sexuality, far from being the essence of 'the natural,' was subject to sociocultural shaping to an extraordinary degree. The importance that culture attributes to sexuality may, therefore, they speculated, not be a result of sexuality's intrinsic significance: society may have had a need *to invent* its importance and power at some point in history. Sexual activities of all kinds, they suggested, were not the results of inbuilt, natural drives or instincts but of complex psychosocial processes of development, and it is only because sexual activities are embedded in social scripts that the physical acts themselves become important. These insights suggested the possibility of exploring the complex processes by which individuals acquired subjective meanings in interaction with significant others and the effects of 'sexual stigma' on these developmental processes (Plummer, 1975).

By the mid-1970s, it is possible to detect the clear emergence of a distinctive sociological account of sexuality, with two related concerns. One focused on the social categorization of sexuality, asking questions about what historical factors shaped the labeling and stigmatization of sexual differences, differences which then appeared as natural, but were in fact cultural. This gave rise to a major effort of historical investigation that has traced the emergence of the idea of the 'invert,' 'intermediate type,' 'third-sexer,' 'homosexual,' or 'gay' – terms have varied at different times – as a distinct type of individual. The other concern was primarily with understanding the shaping of subjective meanings of sexuality through socio-psychological processes and enacting historically shaped sexual scripts, which could explain how individuals defined themselves as sexually different in specific historical circumstances.

Following the approaches pioneered by sociologists and social psychologists such as McIntosh and Gagnon and Simon, a third theoretical element now came into play, represented by the work of Michel Foucault (1976/1979). Foucault's introductory essay on *The History of Sexuality* is often seen, misleadingly, as the starting point of historical and constructionist approaches, but there can be no doubt of the subsequent impact of what was planned as a brief introduction to a multivolume study. Like Gagnon and Simon, Foucault appeared to be arguing that 'sexuality' was a 'historical invention.' Like McIntosh, and others who had been influenced by her, he saw the emergence of the concept of a distinctive homosexual personage as a historical process, with the late nineteenth century as the key moment. The concept of the homosexual was not the result of a neutral scientific discovery. It was produced through discourses that worked simultaneously to invent same-sex subjects and regulate them, through a complex of power and knowledge. The process of medicalization, in particular, was seen as a vital explanatory factor: homosexuality was increasingly defined as a specific psychological or medical condition that distinguished some people from others. Like McIntosh, Foucault suggested that psychologists and psychiatrists have not been objective scientists of desire, as the sexological tradition proclaimed; but on the contrary, they have been diagnostic agents in the process of social definition and regulation. But at the same time, his suggestion that people do not react passively to social categorization – 'where there is power, there is resistance' – left open the question of how individuals react to social definitions. How, in a phrase that now became central to the debate, identities are formed in the intersection of social and subjective meanings.

Sexual Behavior, Sexual Categories, and Sexual Identities

The most crucial distinction for historical and social explanations is between sexual behavior (how we practice sexuality), categories (how sexual types are defined), and identities (how we see ourselves and people like us, and distinguish ourselves from others). Kinsey et al. (1948) had shown that there was no necessary connection at all between what people did sexually and how they identified themselves. If, in a much disputed figure, 37% of the male population had some sort of sexual contact with other men to the point of orgasm, yet a much smaller percentage claimed to be exclusively homosexual, then identity had to be explained by something other than sexual proclivity or practice. Sexual identity as an idea was much more complex than it seemed. It proved, nevertheless, to be a powerful mobilizing idea for those who sought to affirm their sense of self and being through a public identification. By the 1970s, many self-proclaimed homosexuals were 'coming out,' in the wake of the new lesbian and gay movement, and defining themselves very clearly as gay, lesbian, or bisexual. Many of those who came out saw in the historicization of the homosexual category a way of understanding how and why same-sex desire had carried such discrimination, prejudice, and hostility. Others who came out, however, were strengthened in their belief that homosexuality was not only intrinsic to their sense of self and social identity but also expressed a distinctive orientation that was essential to their nature. This difference between seeing it as a useful category and seeing it as an essential part of their makeup was at the heart of the so-called social constructionist–essentialist controversy in the 1970s and the 1980s (Stein, 1992). For many of those who came out, a critique of essentialism could also be conceived of as an attack on the very idea of a homosexual identity, a fundamental challenge to the hard-won gains of the lesbian and gay movement, and the claim to recognition of homosexuals as a legitimate minority group. This was the source of the appeal of

subsequent theories of a 'gay gene' or 'gay brain,' which suggested that sexual orientation was wired into the human individual (Wilson and Rahman, 2005). It is probably the case that the majority of the lesbian and gay world, especially in the United States, strongly believes that a separate, natural orientation is the basis of their identities. It seems to correspond with common sense understandings of how individuals feel about their sexual desires.

It is important to make several clear points in response to these constructionist-essentialist debates, where social scientific debates became a marker of social movement differences. First, the distinction between behavior, categories, and identities need not necessarily require the ignoring of questions of causation; constructionist theory merely suspends them as irrelevant to the question of the social organization of sexuality. Foucault himself stated that : "On this question I have absolutely nothing to say" (cited in Halperin, 1995: p. 4). The really important issue is not whether there is a biological or psychological propensity that distinguishes those who are sexually attracted to people of the same gender from those who are not. More fundamental are the meanings that these propensities acquire, however, or why ever they occur; the social categorizations that attempt to demarcate the boundaries of meanings; and their effect on collective attitudes and individual sense of self. Social categorizations have effects in the real world, whether or not they are direct reflections of inbuilt qualities and drives.

The second point to be made is that terms such as constructionism and roles should not be seen in any deterministic or mechanistic fashion. They are in the end no more than heuristic devices to identify and understand a problem in studying sexuality in general and homosexuality in particular. It is transparently obvious that the forms of behavior, practices, identity, institutional arrangements, regulation, beliefs, ideologies, and even the various definitions of 'sexual' vary enormously through time and across cultures and subcultures. A major objective of historical and social constructionist studies of the erotic has been to challenge the taken for granted, to denaturalize sexuality in order to understand its human dimensions and the coils of power in which it is entwined and how it is shaped by historical forces and events, and by individual and collective agency. This is a continuous process. In the wake of positive lesbian and gay identities, there has been a proliferation of other identities, from bisexual to transgender, which work to trouble the binary divides of heterosexuality/homosexuality and masculinity/femininity.

The third point that requires underlining is that, regardless of evidence for the contingency of sexual identities, this should not imply that personal sexual identities, once acquired by individuals, are irrelevant and can readily be sloughed off. That categories and social identities are shaped in history does not in any way undermine the fact that they are fully lived as real by people. The complex relationship between societal categorization and the formation of subjectivities and sexual identities has in fact been a key focus of writing about homosexuality since the mid-1970s. On the one hand, there is a need to understand the classifying and categorizing processes that have shaped our cultural concepts of homosexuality – the law, medicine, religion, patterns of stigmatization, as well as formal and informal patterns of social regulation. On the other, it is necessary to understand the level of individual and collective reception of, and battle with, these classifications and categorizations – the level of subjectivity and agency. The best historical work has attempted to hold these two levels together, avoiding both sociological determinism (you are what society dictates) and extreme voluntarism (you can be anything you want): neither is true (see discussion in Vance, 1989).

Some of the most interesting work on the tension between sociological determinism and voluntarism has attempted to explore the subcultures, networks, urban spaces, or even rural idylls that provided the terrain, and the conditions of possibility, for the emergence of distinctive sexual identities. McIntosh's suggestion that the late seventeenth century saw the emergence of a subcultural context for a distinctive homosexual role in England has been enormously influential. Her rediscovery of the London mollies' clubs has been the starting point of numerous historical excavations (for example, Trumbach, 1977; Bray, 1982). There is now plentiful work that attempts to show that homosexual subcultures and identities existed before the late seventeenth century – for example, in the early Christian world (Boswell, 1980), or in other parts of Europe (see essays in Herdt, 1994) – just as there have been scholars who have argued that we cannot really talk about homosexual identities until the late nineteenth, or even mid-twentieth centuries. There is a real historical debate. As a result, it would now seem remarkable to discuss sexual identities (and their complex relationship to social categorizations) without a sense of their historical and social context. Sexual *identities* are made in history, not in nature.

Heterosexuality and Homosexuality

Identities are not created in isolation from other social phenomena. In particular, a history of homosexual identities cannot possibly be a history of a single homogeneous entity, because the very notion of homosexuality is dependent, at the very least, on the existence of a concept of heterosexuality, which in turn presupposes a binary notion of gender. Only if there is a sharply demarcated difference between men and women in the culture does it become meaningful to distinguish same sex from other sex relationships. Social constructionism originally paid little attention to the construction of heterosexuality. But without a wider recognition that 'the heterosexual' was also a social construction, attempts to explain the invention of 'the homosexual' made little sense. The two concepts are inextricably married together. One of the early attractions of the first volume of Foucault's *The History of Sexuality* was precisely that it both offered an account of the birth of the modern category of homosexual and put that into a broader historical framework. Foucault did this by postulating the invention of sexuality as a category in Western thought, and in delineating the shifting relationships between men and women, adults and children, and the normal and the perverse as constituent elements in this process. Foucault himself was criticized for putting insufficient emphasis on the gendered nature of this process, but this was more than compensated for by others in their developing of feminist critiques of 'compulsory heterosexuality' or 'the heterosexual institution,' with its own complex history (Rich, 1980; Jackson and Scott, 2010).

Central to these debates on the institutionalization of heterosexuality was the perception that although sexuality potentially takes many forms, the ways in which it is lived are never simply a spectrum where homosexuality and heterosexuality sit equally side by side. Historically, sexuality has been structured in dominance, with heterosexuality privileged, and that privilege is essentially male oriented. Homosexuality has been constructed as a subordinate formation within the 'heterosexual continuum,' with male and female homosexuality having a different relationship to the dominant forms. In turn, once this is recognized, it becomes both possible and necessary to explore the socially constructed patterns of femininity and masculinity as power relationships (Connell, 2009). Increasingly, in a range of disciplines, power came to be seen as the key element that needed to be explored and understood.

Although the constructionist debates began within the disciplines of sociology and history, later developments, taking forward both theoretical and political (especially feminist) interventions, owed a great deal to poststructuralist and deconstructionist literary studies, and to the emergence of 'queer studies.' Whereas history and sociology characteristically attempted to produce order and pattern out of the chaos of events, the main feature of the poststructuralist and deconstructuralist (hereafter poststructuralist) approaches at first was to show the binary conflicts reflected in literary texts. The texts are read as sites of gender and sexual contestation, and therefore of power and resistance (Sedgwick, 1990). Sedgwick's work and that of the American philosopher Judith Butler (1990) were in part attempts to move away from the essentialist/constructionist binaries by emphasizing the 'performative' nature of sex and gender. For Butler, there is no originating 'sex' on which gender differences or the homosexual/heterosexual binary are built. On the contrary, gender differences are shaped by their incessant enactment and repetition. They come to seem so fixed, embedded, and embodied because they are constantly acted out in historically given institutional frameworks.

Such poststructuralist work in turn opened up what might be called the 'queer moment,' which radically challenged the relevance of all fixed sexual categorizations. For queer theorists, the perverse is the worm at the center of the normal, giving rise to sexual and cultural dissidence and a transgressive ethic, which constantly works to unsettle binarism and to suggest alternatives.

Whereas early constructionism sought to explain how meanings and identities were shaped in historical circumstances, queer theory seeks to demonstrate how all fixed concepts are inextricably involved in the flow of power. This theoretical position was separate from but contingently linked to a new outburst of sexual radicalism at the end of the 1980s and the early 1990s, which was both a reaction to the acquired immunodeficiency syndrome crisis on the gay world, especially in the United States, and a growing frustration with what was seen as the conservative, assimilationist tendencies of many gay communities (Warner, 1999). The problem with both the poststructuralist theoretical tendencies and the related new forms of militancy was that they were rooted in very special cultural and political contexts, in highly developed Western societies.

Comparative Perspectives

One of the main lessons of historical analyses of heterosexuality and homosexuality is the recognition that such concepts are peculiar to a very specific historical period, from the nineteenth century onward, in a distinct region of the world, largely Western Europe and North America. Much of the debate about the homosexual/heterosexual binary divide was based on the perceived Western experience. Yet from the beginning, comparisons with non-Western sexual patterns were central to historical and constructionist perspectives, and it was immediately obvious how differently sexuality was lived elsewhere. Foucault (1976/1979) compared the Western 'science of sex' with the non-Western 'erotic arts,' and although he has been subsequently critiqued for his own culture-bound assumptions, his addressing of the 'erotic arts' clearly opened the way to more nuanced analysis.

It was the very fact of different patterns of 'institutionalized homosexuality' on a global scale that had formed the starting point of McIntosh's essay. She identified two key regulating elements that could be observed in different parts of the world. The first was the erotic entanglements between adults and nonadults (as in the intergenerational sex, which denoted the passage from childhood to adulthood in some tribal and premodern societies). The second was based on gender inversion (classically as in the case of the native American 'berdache,' where a sort of third sex was seen as emerging, a pattern that can also be traced in the association of male homosexuality with effeminacy, or lesbianism with hypermasculine behavior). Neither pattern necessarily implies the existence of a particular homosexual condition. For some writers, these patterns are the keys to understanding homosexuality in premodern times. Historians have traced the evolution over time of patterns of homosexual life, which have shifted from intergenerational ordering, through categorization around gender and class, to recognizably modern forms of egalitarian relationships (for a historical perspective, see Trumbach, 1998).

It would be misleading, however, to believe that these broad patterns fully encompass the diverse ways in which sexuality is lived in everyday lives at any particular time. Individual identities and social positions are shaped not only by and at the intersection of a host of often conflicting forces, typically dynamics of class, gender, race, and ethnicity, but also embracing a host of other determining influences including nationality, faith, geography, age and generation, ability and disability, as well as sexuality (Taylor et al., 2010). The interlocking, mutually reinforcing impact of various forms of power and domination around race, gender, and sexuality was first articulated by the US and European–Black feminists as it became clear that the universalizing tendencies of white Western feminist analyses, especially around issues like the family, did not speak to the experience of all women. What their intersectionalist analyses sought to do was to show how such experiences worked together to reinforce one another in the uniqueness of subject position: they were lived not as separate forms of oppression but as inextricably interlocking and densely lived experiences, producing their own forms of resistance. The force of these analyses was to highlight the reality that identification is always complex, that subjectivity is messy, and that personhood is inextricably bound up with

relations of power. Some identities and experience of oppression are more important at some time rather than another, giving rise to different forms of political struggle, and different identities and subjectivities.

If this is true within Western cultures, it is even more relevant when sexuality is viewed within a global perspective. Although Altman (2001) has discussed the emergence of the 'global gay,' which is based on the increasingly generalized characteristics of sexual lifestyles in an increasingly globalized world, there is plentiful evidence at the same time of the different ways in which homosexuality and heterosexuality are lived in different cultures across the world, and where the idea of a fixed orientation is remote from everyday experience.

The forces of globalization are bringing into contestation and confrontation different beliefs, behaviors, and assumptions, and in the process are reshaping the context and meanings of intimacy and the erotic. While these globalizing processes affect all parts of the world, their impact is uneven on individuals, groups, states, and regions because they are enmeshed in huge disparities of power and gross inequalities, and this is manifest in persistent inequities between cultures and in continuing sexual injustices, especially against women, children, and lesbian, gay, or transgendered identified peoples. Globalization in many ways accentuates and dramatizes the inequalities that already existed. Members of new global elites have more in common with each other than with the poor in their own nation states. People with the latest hi-tech gadgets rub shoulders with people who have nothing. The new digital technologies may create new forms of inequality, new desires, wants, and needs, while people lose the comforts of their lost worlds, and are forced defenseless or ill equipped into a global marketplace – including the sexual marketplace. Yet, alongside these dangers are new possibilities of links across difference, not least through the explosion of the Internet and social networking, giving rise to new subjectivities, and to claims to social justice and new discourses of human sexual rights (Aggleton et al., 2012). The growing profile of lesbian, gay, bisexual, transgender (LGBT) issues in political and cultural debates across the globe has had complex and often contradictory effects. From Iran to Zimbabwe, Iraq to Uganda, governments and fundamentalist religious movements have used prejudice against homosexuality to mobilize against perceived Western influences and in favor of a highly selective version of traditional values. At the same time, human rights claims have been advanced to support beleaguered LGBT people, and to produce common identifications and solidarities.

Beyond Constructionism

Historical and social constructionism has advanced and changed rapidly since the 1970s. The 'category' that early scholars were anxious to deconstruct has become 'categories' that proliferate in contemporary societies. 'Roles,' neat slots into which people could be expected to fit as a response to the bidding of the agents of social control, have become 'performances' (Butler, 1990) or 'necessary fictions' (Weeks, 1995) whose contingencies demand exploration. 'Identities,' which once seemed categorical, are now increasingly seen as fluid, relational, and hybrid: people are not quite today what they were yesterday, or will be tomorrow. Personal 'narratives,' stories people tell each other in the various interpretive communities to which they belong, are increasingly seen as critical in shaping our identifications. Individual identities, far from being automatic responses to internal orientations, are negotiated in the ever-changing relationship between self and other, within rapidly changing social structures and meanings (Plummer, 1995, 2003).

There is a paradox here. While historical and constructionist approaches have problematized and deconstructed identities, and shown their social origins, it has not stopped an ever-growing proliferation of identifications and subjectivities. Even heterosexuality, which for so long was the silent norm, so taken for granted, like the air we breathe, that it was rarely articulated, has found a new voice. People now talk more explicitly about their heterosexual orientation as a way of defining themselves against assertive homosexual subjectivities. Among those who for long were disqualified for their sexual or gender nonconformity the change has been more striking. Terms such as queer or omnibus descriptions such as LGBTQI (lesbian, gay, bisexual, transgender, queer/querying/questioning, intersex…, the listing is potentially long) attest to the vitality of sexual and gender identifications and battles over meanings. Sexuality is no longer a destiny, but a focus for defining and redefining a creative life.

Sexual orientation may, or may not, be a product of genetics, psychosocial structuring, or environmental pressures. That issue, which has tortured sexology for over a century, may or may not be resolved at some stage in the future. For those who seek historical and social understanding, however, other questions are central: not what causes the variety of sexual desires, preferences, or orientations that have existed in various societies at different times, but how societies shape meanings around sexual diversity and the effects these have on individual lives. That puts the emphasis where it should be, on human endeavor in ever-changing historical circumstances.

Sexual Politics in the Arab World

Shereen El Feki, London, UK

Abstract

Since the late twentieth century, attitudes toward nonconforming sexualities and gender roles in the Arab region have hardened, a trend fueled by a rise in Islamic conservatism and exploited by authoritarian regimes. Although political cultures have proved slow to change in the wake of the 'Arab Spring,' a growing freedom of expression is opening space for discreet challenges to the sexual status quo, part of wider debates over human rights and personal liberties in the emerging political order.

Introduction

The Arab region, also called the Middle East and North Africa (MENA), is vast and varied – 22 countries, 370 million people, three major religions, dozens of sects and ethnic groups – with as much diversity within states as there is between them. Yet running across these borders are three red lines – subjects not to be challenged in word or deed. The first of these is politics. The events of the 'Arab Spring', with mass uprisings and violent conflict in Tunisia, Libya, Egypt, Yemen, Bahrain, and Syria, have taken a chisel to this line and begun the process of chipping away at received political wisdoms – even if building functioning democracies is proving, in most cases, more difficult than bringing down decades-old dictatorships. The second red line is religion, and in particular, the region's dominant faith, Sunni Islam. That too is coming into question, with increasing public debate over the role of religion in public life, in response the rise and subsequent travails of political Islam in Egypt, Tunisia, and Morocco, and recent gains by Islamic extremists in Syria, Libya, and Iraq.

The third red line is sex. Or more broadly defined, sexuality: that is, the sexual act and all that goes with it, including gender roles and identity, sexual orientation, pleasure, intimacy, eroticism, and reproduction (World Health Organization, 2006). Across the Arab world today, the only socially accepted sexuality is strict heteronormativity, its cornerstone family-endorsed, religiously sanctioned, state-registered marriage. Anything outside of this context is haram (forbidden), *illit adab* (impolite), *'ayb* and *hchouma* (shameful) – a seemingly endless lexicon of reproof (El Feki, 2014).

Public opinion appears to uphold this sexual status quo. In World Values Surveys, conducted between 2010 and 2014, strong majorities across the Arab region rejected homosexuality, abortion, premarital sex as 'unjustifiable.' This pattern is in stark contrast to publics in Western Europe, Australasia, and the United States, where less than a quarter of those surveyed considered such practices unacceptable. Yet on questions of democracy and its importance to their own lives, publics were far more closely aligned, even with popular disenchantment in the aftermath of the Arab Spring (**Table 1**). It remains the case, as scholars Norris and Inglehart observed in 2002, that the gulf separating Middle East and West "involves Eros far more than Demos" (Norris and Inglehart, 2002).

Sex has long been a dividing line between the West and the Arab world. A keynote of the Orientalist critique since the birth of Islam, Arab cultures were occasionally celebrated, but more often denigrated, for their perceived sexual license by more than a millennium of European observers (Said, 1995; Daniel, 1993). Today, positions are largely reversed, with the Arab, and broader Islamic, world widely criticized for sexual intolerance. It is not just social liberals, within and outside the region, who hold this view. It has also become a central plank of the 'Islamophobic' discourse of conservatives in America and Europe, the self-proclaimed last stand

Table 1 Attitudes towards sex and politics, % agreeing with above statements, select countries

	Premarital sex never justifiable	*Abortion never justifiable*	*Homosexuality never justifiable*	*Democracy absolutely important*
Morocco	69.3	71.7	83.6	58.7
Tunisia	n/a	70.4	87.1	57.1
Jordan	86.8	66.0	85.6	43.2

in the battle between 'Western' values and the depredations of 'radical' Islam, particularly as they relate to the rights of women (Saunders, 2013). And the West, once praised by some nineteenth-century Arab observers for its hard line on same–sex relations, is now seen by many within the region as a radiating source of sexual debauchery from which the region must be shielded.

These conflicts play out in international fora, notably at the United Nations, with battle lines clearly drawn over sexual rights: that is, the freedom to access sexual and reproductive health services and to generate, share, and consume ideas and information about sexuality; the right to choose one's own partner and to be sexually active, or not, in consensual relations; the freedom to decide whether to have children, and when; the right to control one's own body and the liberty to pursue a satisfying, safe, and pleasurable sexual life, without coercion, discrimination, or violence (IPPF, 2008).

Since the 1994 International Conference on Population and Development in Cairo, civil society and governments around the world have struggled to enshrine sexual rights in international agreements, in the face of strong resistance from Arab states, collected under the umbrella of the Organization of Islamic Cooperation (OIC). More recently, further alliances have formed with member states of the African Union, as well as the Vatican and its allies, to oppose recognition of rights on the basis of sexual orientation and gender identity, and to enshrine the legitimacy of 'traditional values' in international contexts. Some of the longest-standing struggles are over the Convention on the Elimination of all Forms of Discrimination Against Women (CEDAW); while 20 of the 22 Arab states have ratified or acceded to the Convention, almost three-quarters of these have also lodged reservations to assorted articles, largely on the grounds of potential conflict with shari'a, which informs the majority of their constitutions. Egypt's Muslim Brotherhood spoke for many conservative opponents in the region when it attacked recent attempts to strengthen CEDAW's provisions as a slippery slope to free love, homosexuality, prostitution, in an effort to 'destroy Islamic ethics,' 'demolish the institution of the family,' ending in 'the last step of intellectual and cultural invasion.'

The rise of Islamic fundamentalism in the Arab region since the 1970s has significantly hardened, and politicized, attitudes toward gender roles and sexuality, for both men and women. While gains have been made in a number of countries on aspects of sexual and reproductive rights, particularly as they relate to marriage (for example, Morocco's 2004 revisions to the *Moudawana*, or family law code, and Egypt's 2008 amendments to the Child Law), these were largely introduced by authoritarian regimes in the absence of wider political, economic and social reforms recognizing and respecting fundamental human rights. The calls for justice, freedom, and dignity which mobilized millions during the Arab Spring – as well as equality, autonomy, integrity, and privacy – are as yet, unanswered and whether such reforms will extend to sexual and reproductive rights remains to be seen. This is a pressing issue for two populations outside the staunchly defended citadel of marriage, on the sharp end of political and social regulation: unmarried youth, and lesbian, gay, bisexual, transgender/transsexual, queer (LGBTQ) men and women.

Youth, Sexuality, and Marriage

Marriage is a pivotal rite of passage for the estimated 100 million people between 15 and 29 years of age in the Arab world (Dhillon and Yousef, 2009). Early marriage remains a risk for poor, less educated, and rural girls across the region – particularly those in desperate circumstances, such as Syrian refugees trafficked into sex work (masquerading as short-term marital unions) by their impoverished families. However, early marriage and motherhood, which was the norm in the most of the region two to three generations ago, is a declining phenomenon, even in countries such as Yemen where tradition and religious conservatism have long militated against setting 18 as the minimum legal age of marriage (UNFPA, 2012).

It is the other end of the singulate mean that is now a widespread source of concern. The singulate mean age of marriage is rising in most of the Arab region, in some cases dramatically: in Morocco, and Tunisia, for example, on average women are first marrying in their late 20s and men in their early 30s (**Table 2**). This delay is due in part to economics, matrimony having become an expensive proposition in the consumer-culture economies of Arab region. Tradition and religion dictate that men and their families cover the costs of marriage, from the big white wedding and beyond, but double-digit unemployment among youth – a major driver of the recent uprisings – means that men are obliged to wait to tie the knot.

At the same time, significant advances in female education, and the small, but growing, presence of women in the workplace is also pushing up the age of marriage of women. Indeed, there is rising moral panic in many countries over the phenomenon of *'anusa*, or spinsterhood – educated women who fail to find a husband, and therefore remain at home, dependent on their families. Divorce is causing similar social anxiety, particularly in the wealthier Gulf states that fear a rising tide of family disintegration and a loss of national identity in the face of mass migration of foreign workers to their rapidly developing economies.

Nuptiality is never very far from politics. In the United Arab Emirates (UAE), for example, government-sponsored marriage funds offer financial subsidies to promote intra-Emirati weddings (in the hope of discouraging marriage with foreigners), and provide further support services in an effort to stave off divorce. Elsewhere, notably Lebanon, legal restrictions on individuals marrying outside their religious or ethnic group within the country, or prohibiting women from passing nationality to their foreign husbands (or the children of such

Table 2 Mean age at first marriage

unions) face growing challenge from civil society. Nonetheless, fears of the decline of marriage are greatly exaggerated: beyond the headlines, official statistics show that the vast majority of people in the Arab region get, and stay, married, though they are waiting longer now to do so.

As a consequence, there are more single youth in the region than ever before. This is a generation caught between biology and sociology, reaching sexual maturity in a climate that is reluctant to countenance any alternative to sex within marriage. Given rising religiosity among much of the region's youth, a significant but highly speculative number are also turning to alternative forms of marriage within Islam, among them *mut'a* (temporary 'pleasure' marriage, permitted under Shi'i Islam) and *'urfi* (so-called customary marriage, increasingly popular in Sunni-majority countries) in an attempt to give their sexual relations a religious cover, however controversial (Hasso, 2010). For most young people, however, these remain more of a last resort than a lifestyle choice.

Official reluctance to fully face up to this cultural and demographic dilemma makes research on youth sexuality often difficult. However, a window is opening, thanks to human immunodeficiency virus (HIV). From a low base, the Middle East and North Africa (MENA) is now one of only two world regions where HIV is still on the rise: new infections and acquired immunodeficiency syndrome (AIDS)-related deaths have doubled over the past decade (UNAIDS, 2014; **Table 3**). Over the past decade, HIV has provided the socially acceptable context of public health to ask unmarried youth hard questions about their sexual knowledge, attitudes, behaviors and practices.

In Morocco, Algeria, Tunisia, Jordan, Lebanon, West Bank – anywhere large-scale quantitative studies have been conducted – a similar pattern emerges: upwards of half of young men say they are sexually active before marriage, generally making their debut in their mid-to late teens and taking multiple partners along the way. Condoms are rarely used, in large measure because of their popular association with *zina*, which is religiously proscribed sex outside of marriage (El Feki, 2014).

Table 3 HIV/AIDS in the Middle East and North Africa, 1995–2013

Year	*People living with HIV (median estimate)*	*AIDS-related deaths (median estimate)*
1995	42 000	1600
1996	50 000	2100

In general, far smaller percentages of young women are willing to admit to premarital sex. This is due to the primacy of female virginity. Sex before marriage is legally prohibited for both sexes – at least on paper – in more than fourth-fifths of Arab states, but law does little to influence people's sexual behavior anywhere in the world. Rather it is patriarchy, buttressed by religious conservatism, that maintains a pervasive double standard, in which women are expected to turn up on their wedding nights with their hymens intact, but men who have sex before marriage are largely indulged.

Indeed, female virginity is rarely a private matter in communities across the region, but instead a source of collective concern and family (particular male) reputation. Increasing reports of honor killing – in Jordan and the Palestinian Territories, for example – are part of a spectrum of gender-based violence across the Arab region coming to light; recent national surveys in Morocco and Tunisia, for example, show that more than a third of young women have experienced violence at some point in their lives, usually at the hands of family members (Haut Commissariat au Plan, 2009; Office National de la Famille et de la Population, 2010). Indeed, families expend enormous attention and effort on the hymen, this precious piece of female anatomy. Among the tools at their disposal is female genital mutilation, thought to 'cool' a woman's sexual drive; widely practiced in countries bordering the Red Sea, and northern Iraq, its capital is Egypt, where more than 90% of ever-married women aged 15–49 have been circumcised (UNICEF, 2013).

Restrictions on girls' physical activity and social mobility are another means of control; virginity testing is also practiced, including age-old customs (such as *dukhla*, in which a bloodied wedding bedsheet is taken as proof-positive of defloration) and modern medical exams, imposed by families and even, in the case of post-Arab Spring Egypt, by the state in order to discipline female protestors. Research shows that young people themselves both uphold, and subvert, this convention by resorting to nonvaginal intercourse, with high rates of anal and oral sex, as well as hymen repair (El Feki, 2014).

Such is the taboo around youth sexuality that it's not just the end, but also the perceived means that are rejected. There is, for example, widespread resistance to sexuality education in schools, despite ample evidence of ignorance among children, as well as their parents, and confusion compounded by the common consumption of Internet porn. Similarly controversial is the provision of sexual and reproductive health services, including contraception and abortion, to unmarried youth.

Laws and government policies are proving slow to change. In spite of all these obstacles, however, women and men across the region are challenging constraints, albeit working along the grain of culture and tradition. In Morocco, for example, civil society is pushing for a gradual liberalization of abortion laws, currently restricted in the vast majority of Arab countries, yet practiced illegally nonetheless, with an estimated 1.7 million unsafe procedures annually in the Middle East and North Africa (World Health Organization, 2011; Evrard, 2014). Morocco is also home to groundbreaking nongovernmental organizations (NGOs) helping unwed mothers to find jobs, reunite with their families and, critically, stay with their children.

On sexuality education, Lebanon is one of a handful of countries in the region working toward a national 'life skills' curriculum (including wide-ranging instruction on sexual and reproductive health), no easy task given teacher embarrassment and other impediments; elsewhere, programs such as Muntada Jensaneya (Arab Forum for Sexuality, Health and Education), among Palestinian communities in Israel, are finding innovative ways to communicate the facts of life in and out of the classroom.

In Tunisia and Egypt, government-sponsored 'youth-friendly' clinics are working to provide reproductive health information and services, with mixed results, in part because of healthcare provider prejudice. More successful is youth-to-youth education, such as the Y-Peer network, under the aegis of the United Nations Population Fund of UNFPA, the United Nations Population Fund (formerly known as the United Nations Fund for Population Activities), with chapters across the region, in which young people provide one another with information on sexual health. And there is also increasing action by civil society groups to tackle gender-based violence, be it pressuring governments to pass legislation (as in Egypt, against sexual violence in public spaces, in Lebanon against domestic abuse and in Morocco on rape), empowering young women on the streets, holding police to account for sexual abuse, or working with young men to understand, and prevent, such violence at its roots.

An explosion in social media since the Arab Spring is also fostering unprecedented challenges to the sexual status quo. Most dramatic, and arguably least successful, have been the FEMEN-inspired postings of nude photos by young Tunisian and Egyptian women. While acting in the name of freedom of expression and bodily autonomy, these incidents have invoked the ire, not only of religious conservatives, but of political liberals as well (Sboui, 2014). More discreet challenges to authority are proving less divisive, among them Morocco's Facebook protest against the arrest of two teenagers for kissing in public, or Lebanon's playful 'Strip for Jacky' campaign against the dismissal of one the country's Olympic athletes on charges of indecency. Recent years have also seen the emergence of new sources of accurate information, and reasoned discussion, in Arabic on sexuality – notably Al Hubb Thaqafa, a pioneering pan-Arab website which harnesses the power of Facebook, Twitter, and YouTube to stimulate informed and respectful debate about sex, not just as a problem to be managed, but as a pleasure to be celebrated – an openness not seen since the golden age of Arabic erotica a millennium ago.

LGBTQ Populations

Also under pressure is the estimated 2–3% of the region's population who have sex with their own sex or have a different gender identity – some (though by no means, all) of whom self-identify as LGBTQ, that is, lesbian, gay, bisexual, transgender/transsexual or queer (Abu-Raddad et al., 2010). Stigma, discrimination, and violence – by the state, communities, and families – is pervasive. While patriarchies pump up the pressure on women, the rise of Islamic fundamentalism in recent decades has also narrowed the line on what it means to be a 'real man.' There is little tolerance for appearance or behavior perceived as 'gay' in most quarters, and the age-old prejudice against the passive, penetrated male lives on.

Contemporary mainstream Sunni and Shi'i thinking condemns both male and female homosexual acts. Despite a history of more open interpretation by religious scholars within the region, and a lively debate in today's wider Islamic world on possibilities of accommodating same–sex relations, very few Arab voices – notably Tunisian and Syrian academics – openly argue for alternative approaches within the region's dominant faith (Kugle, 2010). Nor is this a uniquely Muslim phenomenon; the many Christian Churches, and conservative Jewish sects, of the region take a similarly hardline against those who break the heteronormative mold.

Politics adds fuel to the religious flame. Within the region, homosexuality has become a weapon in political battles in post-Arab Spring: as an accusation, used by both Islamists and their more ostensibly secular counterparts in Egypt, Tunisia, and Syria, to tar opponents; and as yet another tool to prop up political power by resisting any challenge to the sexual or social status quo as a Western-inspired, if not directly organized, attempt to undermine 'traditional' Arab and Islamic values. In recent years, the status of alternative sexual orientations and gender identities has become a hallmark of liberal democracy. As a consequence, Western aid conditionality, while not yet openly applied to the Arab region, is serving to further strengthen the association of LGBTQ rights with a 'foreign' agenda, fusing homo- and xenophobia in a volatile mix. The question of homo- and transsexual rights has even entered the long-running Arab–Israeli conflict, with a fierce debate on comparative freedoms for LGBTQ individuals on either side of the fence, and their bearing on the legitimacy of a future Palestinian state.

This popular and politically expedient association poses a particular challenge for civil society in the Arab region, whose work largely depends on foreign funding. There are now more than dozen NGOs working to empower LGBTQ populations, scattered across Morocco, Algeria, Tunisia, Egypt, Palestine, Northern Iraq, and Lebanon, the epicenter of LGBTQ civil society, with almost half-a-dozen groups offering information, support and other services. While still relatively few in number, and with an outreach still largely limited to educated, middle class men and women, this is a threefold increase in activity across the region since 2010. Such growth is due in large measure to an increasing willingness on the part of young activists to test the boundaries of freedom of expression and assembly, even in the face of rising political Islamism (as in Morocco), a clampdown on civil society (as in Egypt), and violent conflict in much of the region.

Social media is key to this development. Online sites and apps, such as GayRomeo and Grindr, are popular with gay men across the region; Facebook and other Internet fora are particularly valuable for the minority of women with access to the Internet, whose physical and social ambit is far more constrained by family and community control than that of their male counterparts. And it has also transformed collective organization, in sexuality as in politics. The granddaddy of all LGBTQ organizations in the region, Helem, based in Lebanon, grew out of an online discussion group in the mid-2000s. Some of the newest groups exist only online – in the form of Internet magazines, as in Morocco, or online radio, as in Algeria – providing information, support, and opportunities for discussion rarely available in Arabic, even on, socially accepted married sexual life. Other groups, such as Al Qaws and Aswat, supporting queer Palestinian

women, Meem has closed doors, mirror their extensive on-the-ground activities with a strong online presence. While technology opens new doors, it also presents new challenges: in particular, online security, and the urgent need to protect activists, be it from police entrapment or family outrage.

Such Internet Internet activity complements several offline regional initiatives launched since the beginning of this decade. Among them is the Arab Foundation for Freedoms and Equality (AFE), which trains human rights advocates, particularly those with an interest in LGBTQ rights; the Regional Network on HIV/AIDS for men-who-have-sex-with men (M-Coalition); and MantiQitna, an annual retreat for LGBTQ activists from across the Middle East and North Africa, focused on networking, capacity building, and advocacy. These collaborations are part of a broader strategy by LGBTQ activists to address the violence, stigma, and discrimination experienced by their peers by weaving their message into wider efforts secure fundamental human rights for all, rather than an exclusive focus on a sexual identity politics. In Tunisia, for example, several new NGOs, working on recognition and respect for personal freedoms, and minority rights, have incorporated alternative sexualities and gender identities in their purview from the outset.

Law is a major challenge. More than four-fifths of countries in the Arab region have penal codes that explicitly criminalize homosexual acts. Some, like that of Sudan, specify male sodomy; others, like that of Algeria, sanction both male and female same–sex relations; others, as in Lebanon and Syria, condemn sexual relations "against the order of nature" (Al Farchichi and Saghiyeh, 2009). Burdens of proof vary widely, and it is usually poor men on the receiving end of the state's attention. Punishments can range from fines and imprisonment to the death penalty, in the case of Sudan, Saudi Arabia, and Yemen where strict interpretations of shari'a are the law of the land.

Nor are men and women necessarily immune in the few Arab states, among them Jordan and the West Bank, without specific articles outlawing homosexuality. In Egypt, for example, legal provisions on 'habitual debauchery' and prostitution are routinely used to prosecute gay men, most famously in the Queen Boat incident of 2001 and more recently in the arrest of more than 70 homosexual men and male-to-female transgendered individuals, swept up in a politically motivated crackdown in the run-up to the 2014 presidential elections. In Iraq there is as yet no state prosecution of homo- or transsexual men and women, yet they face gruesome reprisals and rough justice in Islamist-dominated strongholds beyond government control.

The law can punish in subtle ways as well. Legal codes and policies across the Arab region that penalize sex work and vaguely defined 'public indecency' or HIV infection among migrant workers, or consensual adult sexual activity outside of marriage, or the provision of sexual and reproductive health information, have a disproportionate effect on women and sexual minorities. And then there is sanction through inaction: for example, bureaucratic foot-dragging and red tape which prevents transsexual men and women from changing their sex on official documents, thereby exposing them to a range of difficulties, including prosecution where the law punishes transgendered appearance or behavior, as in Kuwait. Or, more commonly, a failure on the part of authorities to protect those who cross the heterosexual line from verbal or physical abuse, blackmail, job dismissal, and other human rights violations, especially when the perpetrators are within the family or tribe, bedrock of Arab societies.

In the current political climate, changing the law on the books is difficult – all the more so in countries with new constitutions, such as Egypt, Libya, and Iraq, which invoke Islam as a cornerstone. Nonetheless, the experience of NGOs in Lebanon shows that it is possible to mitigate the law in practice. For example, ongoing, informal interaction between Helem and police and lawyers, along with raising awareness of LGBT individuals of their rights, is relieving some of the pressure. And in the courts, strategic litigation is turning the law on its head: over the past 5 years, two landmark cases, involving a gay and transgendered man, have seen judges in Lebanon rule that Article 534, with its condemnation of sexual acts "contrary to nature" does not apply to such individuals who fall within the spectrum of nature's rich variety (Jernow, 2011).

Health is another problem as well as a point of progress. Men-who-have-sex-with-men are among the hardest hit by the region's emerging HIV epidemic, with infection rates exceeding 10% in a number of countries. Treatment rates are also the lowest in the world, with fewer than 20% of those in need of anti-retroviral therapy receiving the medication they require (UNAIDS, 2014) As with youth populations, HIV is paving the way to quiet government approval for research, funding, and outreach to vulnerable groups, including male and female sex workers. Public health also allows religious leaders, who are key to shifting mainstream attitudes, to constructively engage on questions of homo- and transsexuality, although translating these conversations into positive action from the pulpit, or the minbar, is an ongoing challenge.

Ironically, the biggest single health challenge facing LGBTQ men and women are health-care providers themselves. Homophobia is rife: one study in Lebanon, for example, found that more than half of physicians surveyed refused to treat homosexual men, preferring to send them onto psychiatrists for reparative therapy, also a popular practice in Egypt and the Gulf (Al-Kak, 2009). Again, NGOs are slowly changing the landscape. Lebanon is home to Marsa, the Arab region's first LGBTQ-friendly sexual health clinic, and similar operations are taking root in other countries, among them Morocco. Outreach to doctors is also bearing fruit. Last year, for example, the Lebanese Psychiatric Society openly condemned reparative therapy as malpractice, putting in place measures to discipline its practitioners. And Lebanese physicians themselves have also banded together in a new NGO to combat stigma and discrimination against LGBTQ patients.

Media is also key to shaping views. Mainstream press, movies, talk shows, and soap operas in the Arab region generally take a dim view of homo- and transsexuality. Such attitudes are reflected in language, *shadh* or 'deviant' being the most common term used to describe men-who-have-sex-with-men. One of the notable successes of LGBTQ activists in Lebanon has been to shift media to more neutral terms, such as *mithliyya* for homosexuality. Lebanon is now home to one of the few openly gay performers in the Arab region and its authors and filmmakers are part of small but growing trend – noticeable also in North Africa – toward more sympathetic and nuanced portrayals of alternative sexualities and gender identities.

In Egypt, for example, most press were quick to curry political favor and align with government officials in condoning the 2014 arrests of homo- and transgendered men, who were left to languish in prison in the absence of popular pressure for their release. In contrast, thanks to civil society, a 2013 TV program featuring homosexual men caught in flagrante at a gay cruising cinema in Beirut had different outcome. Following the broadcast, police raided the venue, arresting 30 mainly poor, migrant workers, who were then subjected to anal examinations – a scientifically and ethically dubious forensic technique to 'prove' homosexual acts, popular across the Arab region. However, other Lebanese media, with which Helem had worked on such issues, were quick to denounce the tests. As a result, not only were the men released, but the country's national medical association also condemned the practice, threatening to strike off any doctor implicated; the Ministry of Justice subsequently issued a circular instructing police to cease and desist from such procedures, a welcome step towards eliminating the practice.

Conclusion

Among the more remarkable pieces of graffiti in Cairo following the 2011 uprisings was a cartoon of two mustachioed men, in policemen's caps, kissing each other, under the slogan, 'Cops are Gays.' Given recent clashes between protesters and security forces, this was intended as an insult, not a sociological observation. Within days, however, unknown artists had transformed the moustaches into rainbows and replaced the hate-filled text with a more constructive insight: 'Homophobia is not revolutionary.'

If only it were as easy to change attitudes on the ground. The Arab world is by no means alone in its sexual dilemmas, as recent furores over homosexuality in Uganda, sexual violence in India, or abortion in Spain clearly attest. But some features stand out. Across the region, sex is bound up in shame – particularly for women – which makes it a powerful tool of political and social control. Sexual freedoms are hard to exercise when family interests trump individual choice. And when appearance counts for more than reality – when virginity is defined by a piece of anatomy rather than a state of chastity, for example, or when prostitution masquerades as marriage.

While there have been small gains in sexual rights since the Arab Spring, there are limits to growth, even in as relatively open an environment as Beirut, when sexuality remains a taboo; when women's rights are curtailed, in law as well as practice; when youth unemployment limits autonomy; and when fundamental political, economic and social rights are still far from reality for all but an elite across the Arab region. Bringing sexuality into the broader debate on individual rights and personal freedoms is key to ushering in change in both political and personal life. But that is the work of a generation at least.

Sexual Risk Behaviors

Leickness C Simbayi, Human Sciences Research Council, Cape Town, South Africa; and Psychiatry and Mental Health, The University of Cape Town, South Africa

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Sexual risk behaviors place either of the sexual partners involved at increased risk of some negative health outcomes such as increasing the chance of acquiring or transmitting disease especially sexually transmitted infections including human immunodeficiency virus or having an unwanted pregnancy. They include early sexual debut, unsafe sexual practices such as having unprotected (i.e., without a condom) vaginal, anal, and oral sex, having multiple sexual partners, engaging in group sex, engaging in dry sex or vaginal douching, and having sex while bleeding. There are also some culturally sanctioned sexual risk behaviors. Safer sex practices such as abstinence, sexual fidelity, and condom use offer solutions to avoid the negative health outcomes mentioned.

Introduction

Sexual risk behaviors encompass all those practices associated with sexual intercourse irrespective of sexual preferences that place either of the sexual partners involved at increased risk of some negative health outcome such as increasing the chance of acquiring or transmitting disease especially sexually transmitted infections (STIs) including human immunodeficiency virus (HIV) or an unwanted pregnancy. Common sexual risk behaviors include early sexual debut, unsafe sexual practices such as having unprotected (i.e., without a condom) vaginal and anal sex, unprotected oral sex, having multiple sexual partners, and engaging in group sex, dry sex or vaginal douching, and having sex while bleeding (Leclerc-Madlala et al., 2009). In addition, using unreliable methods of birth control, or using birth control inconsistently also constitutes sexual risk behavior as it increases the risk of occurrence of unwanted pregnancies. These behaviors facilitate STI/HIV transmission through mixing of blood, sperm, and vaginal fluids between or among sexual partners whereas pregnancies result from the fertilization of eggs in females by sperm from males after engaging in sexual intercourse (UNAIDS, 2013). STIs themselves have serious consequences such as (1) increasing the risk of HIV acquisition threefold or more; (2) stillbirth, neonatal death, low birthweight and prematurity, sepsis, pneumonia, neonatal conjunctivitis, and congenital deformities; (3) cervical cancer; and (4) pelvic inflammatory disease, adverse pregnancy outcomes, and infertility (WHO, 2013), while unwanted pregnancies are limited to numerous maternal and child health problems (WHO, 2005). This article focuses primarily on sexual risk behaviors associated with STIs including HIV, and leaves out those linked to unwanted pregnancies as the two sets of behaviors are largely identical in nature. It concludes by discussing safer sex practices such as abstinence, fidelity, and condom use that are known to reduce acquiring or transmitting disease especially STIs including HIV as well as unwanted pregnancies.

Early Sexual Debut

Initiating sex at an early age increases lifetime risk to HIV (UNAIDS, 2013) and has also been linked to other HIV risk factors including alcohol use, having unprotected sex, unplanned pregnancy, and having multiple sexual partners (UNAIDS, 2013). Possible explanations for young people to engage in early sex include peer pressure, low self-esteem, pessimism, sexual coercion, and transactional sex (see Shisana et al., 2009). Others include exposure to television programs with plots around love, sex, and money (Ankomah et al., 2011). Infection occurs primarily due to tearing and bleeding that occur during sex because of the immaturity of adolescent females' reproductive organs. Furthermore, early sexual debut implies that the potential period of exposure to STIs/HIV is lengthened because it is linked to more frequent sexual intercourse, more lifetime STIs, and more sexual partners (Donenberg et al., 2003). Typically young people who have sex at an early age know very little about their own sexual and reproductive health let alone how to protect themselves from acquiring STIs and HIV as they tend to have unprotected sex. Early sexual debut is also linked to less consistent contraceptive use (Geary Waszak et al., 2008) and unplanned pregnancies (Baumgartner et al., 2009).

Unprotected Vaginal Sex

One of the sexual risk behaviors that people of all ages engage in all over the world is having unprotected sex (UNAIDS, 2013). That is, they either do not use male/female condoms correctly and consistently every time they have sexual intercourse as they feel they can trust their sexual partners. If either of the sexual partners is infected with either a classical STI such as trichomoniasis, chlamydia, gonorrhea, human papillomavirus (genital warts), syphilis, genital herpes, or HIV the risk for the uninfected partner to also become infected is high. Among the main reasons for the poor use of condoms that is observed is the prevailing negative attitude toward condom use among both partners. Furthermore, and perhaps more important is the poor access to condoms, especially female ones, which are generally more expensive than male ones (Guerra and Simbayi, 2014). In addition, condom use with primary partners – either spouses or steady partners – tends to be lower than condom use with nonregular partners as well as being lower among older persons (Peltzer et al., 2012; Shisana et al., 2009).

Unprotected Anal Sex

Unprotected anal sex regardless of sexual preferences is also considered sexual risk behavior (UNAIDS, 2013). While it is a common sexual practice among men who have sex with men, it is not as widely practiced among heterosexual couples although it is believed to occur worldwide as part of normal sexual behavior (e.g., see Halperin, 1999). There is a need to highlight the risk for STI/HIV associated with this sexual behavior, if practiced unprotected, i.e., without condoms. More disturbing is that female adolescents avoid vaginal sex to retain their virginity but unfortunately engage in heterosexual anal sex instead under the misguided belief that anal sex is not as risky as vaginal sex (Leclerc-Madlala, 2001, 2002).

Although usually denied, anal sex between men in prison takes place in most countries especially where no conjugal visits are permitted (UNAIDS, 2013). Thus, unprotected sexual intercourse among incarcerated men, whether coercive or consenting, puts those involved at risk for STI/HIV infection. In accounts of prison sex, where sexual favors are used in exchange for cigarettes, drugs, or protection from violence and death, incarcerated adolescents more frequently report previous sexual intercourse, intercourse with multiple sexual partners, rape, gang rape, and inconsistent condom use. As a result of their higher lifetime numbers of sexual partners and their failure to use condoms, youth in detention have higher rates of STIs. Upon release from prison, the victim is likely to transcend his aggressive sexual attitude to raping other members of his community in an attempt to regain his manhood. Given the unwillingness of many authorities to acknowledge that unprotected anal sex is fairly common among men held in prisons, and to make condoms available for use in such institutions, prisons continue to be major breeding grounds for new STIs/HIV infections.

Unprotected Oral Sex

Oral sex involves giving or receiving oral stimulation (i.e., sucking or licking) to the penis (fellatio), the vagina (cunnilingus), or the anus (anilingus) (CDC, undated). People can also acquire or transit STIs/HIV via oral sex although it is a much lower risk activity than sexual intercourse involving vaginal or anal sex, especially for the recipient. This is only true, of course, if the person giving the oral sex has no sores in their mouths or the person receiving it either bleeds or has sores on their sex organs. Similar precautions such as use of condoms or dental dams can be taken during oral sex to prevent STI/HIV infection via this route.

Intergenerational Sex

One very common practice found in many countries in the world involves young girls having sex with men who are their seniors by more than 10 years (UNAIDS, 2013). This is also known as age mixing. Intergenerational sex relationships are mainly driven by poverty where young girls are attracted by material rewards from the older partner (Leclerc-Madlala, 2008; Ott et al., 2011). The promise of gifts and other financial and social benefits, including the potential for upward social mobility, can affect early sexual debut and motivate girls to engage in age-disparate sexual relationships, transactional sex, or marriage at a young age (UNICEF, 2013). This practice of early or arranged marriages is common among various cultures throughout the world as well as in some religions. Where HIV prevalence is high, these factors combine with increased biological vulnerability, limited knowledge about HIV, and low-risk perception to enhance the risks and limit the choices girls and their families make. Given the fact that it currently takes approx. 10–12 years between initial infection and the manifestation of AIDS, most young women in Southern Africa can be assumed to have been infected with HIV during their early teens. Secondly, young girls are often coerced by older men including male schoolteachers into having their first sexual experience with them thus putting them at risk for STI/HIV infection (Shell and Zeitlin, 2000).

Coital Bleeding

There are some reports of people in South Africa engaging in sex when there is blood. The bleeding occurs for different reasons ranging from menstruation by the female, physical injury to the vagina or vaginal walls during intercourse, or STIs such as genital ulcers. Clearly such behavior puts those involved at risk for STIs/HIV infection (Kalichman et al., 2006; O'Farrell and Hoosen, 2007). This probably also occurs worldwide albeit at times inadvertently. There is therefore a need to either promote condom use or to refrain from sex when there is such genital bleeding.

Multiple and Concurrent Sexual Partnerships

Having multiple sexual partners, whether concurrently or through serial monogamy with a high turnover of sexual partners increases the likelihood of exposure to STIs/HIV infection through expanding sexual networks. This is because the likelihood of HIV transmission in sexual networks increases as a result of high viral loads that occur in the early phases of new HIV infection. Having concurrent sexual partners is thought to exacerbate this risk (Halperin and Epstein, 2007; Mah and Halperin, 2010). However, it has recently been argued that concurrency does not fully explain the high HIV epidemic in Sub-Saharan Africa (e.g., see Lurie and Rosenthal, 2009; Sawers and Stillwagon, 2010). In particular, Sawers (2013) has argued that concurrent partners do not raise individuals' risk of acquiring HIV any more than having a nonconcurrent partner. This is because the contributory effects of concurrency appear to be diminished in high HIV prevalence settings where cultural heritage of polygyny also still tends to legitimize sex through informal concurrent partnering among males (see Leclerc-Madlala et al., 2009). Nevertheless, it remains crucial to reduce exposure to multiple sexual partnerships, irrespective of concurrency (Tanser et al., 2011).

Although not substantiated, group sex involving a person who is infected by an STI or HIV should also have a similar effect (Sam Friedman, self-communication 2012). Just as in the other instances described, it is imperative that people engaged in such behavior also use condoms correctly and consistently whenever they engage in sexual intercourse.

Sex Work

Sex work or prostitution involving both sexes occurs in many countries throughout the world. In some countries where sex work is illegal, it occurs underground. Sex workers have few or no rights and are taken advantage of by those who pay for their services. Even in countries with high HIV prevalence, those who pay for their services will often insist on paying more to have unprotected sex than use condoms to protect themselves from STI/HIV infections. Consequently, female sex workers also end up becoming pregnant and are in turn forced to terminate their unwanted pregnancies. One of the ways to reduce the risk on unprotected sex involved in sex work is through legalizing sex work and ensuring that sex workers are provided with health education including the need for correct and consistent use of condoms (UNAIDS, 2013).

Dry Sex or Vaginal Douching

Dry sex or vaginal douching involves cleaning the vagina with either a variety of substances including antiseptics and detergents or inserting traditional herbs into the vagina and drying it with paper or cotton prior to or after having sexual intercourse (Louria et al., 2000; Morar et al., 2003). Some drying and tightening agents are used as 'love potions' to retain the affections of a partner. Dry sex is meant to increase the pleasure that men derive during sexual intercourse. This is because vaginal wetness is seen as indicative of female infidelity, uncleanliness, possible infection, and looseness on the part of the woman rather than natural preparedness to have sex (see Leclerc-Madlala et al., 2009). The main problem with this practice lies with the fact that douching disturbs the vaginal flora or causes extensive local irritation and inflammation of vaginal walls thereby enhancing the sexual transmission of HIV infection (see Leclerc-Madlala et al., 2009). Unfortunately such practices still exist even today thus putting women at risk of STI/HIV infection.

Substance Abuse

There is growing evidence of the strong link between substance abuse especially alcohol and HIV/STI infection (Kalichman et al., 2007; Parry et al., 2010, 2009). Indeed, unwanted pregnancies have also been attributed to substance use. According to this hypothesis, alcohol intake increases sexual risk-taking behavior. Accordingly, the argument has been that when alcohol, and any other illicit drug is consumed in excessive amounts, it inhibit people's ability to engage in safer sex practices such as using condoms correctly and consistently. Thus, persons under the influence of alcohol or other illicit drugs are unable to protect themselves from being infected by HIV/STIs when having sexual intercourse with an infected person. With both alcohol and drug use on the increase globally, the HIV/STIs via this route are also bound to increase. In particular, the use of 'hard' drugs such as cocaine, amphetamines, heroin, mandrax (i.e., Methaqualone), and cannabis is most problematic, particularly among youths (see Peltzer et al., 2009). There is therefore a need to emphasize the links between alcohol or illicit drug consumption and unsafe sex among young adults in order to prevent the spread of HIV/STI infection as well as preventing unwanted pregnancies.

Cultural Rites of Death

There are two main customs that are widely practiced by most indigenous cultures especially in Sub-Saharan Africa. The first is known as *levirate*. This refers to a situation in which the brother of a deceased man is obliged to marry his brother's widow, and the widow is obliged to marry her deceased husband's brother (e.g., for a brief discussion about this practice in Swaziland, see Nxumalo, 1999). The second is known as *sororate*. As noted earlier, a widower or sometimes a husband of a barren woman marries his wife's sister in order to ensure that the relationship developed by the two families produces some offspring and hence does not dissolve (also see Nxumalo, 1999). In the case where one partner in the new relationship is infected with HIV, it increases the risk of the new partner to become infected. This is especially so when the departed spouse died because of an AIDS-related illness.

Indigenous Healing Practices

In most countries in Sub-Saharan Africa and indeed throughout the world, modern (i.e., western) and traditional (i.e., indigenous) healing systems co-exist side by side (see Hopa et al., 1998). Even though the western system is dominant in terms of both official status and scientific acceptability, indigenous healing practices are more widely accessible and used due to pervasive traditional health beliefs, which are followed particularly by people who live in rural areas with poor western medical services. Consequently, an overwhelming majority of the populations of most if not all of the countries in Sub-Saharan Africa and also in many other places throughout the world consult with traditional healers for treatments of most ailments. More interestingly, many people have found a way to utilize what both systems have to offer to them. One of the indigenous healing practices that is thought to be partly responsible for the spread of HIV infection involves the healers either having sex with many of their clients or recommending that their clients should have sex with virgins as part of some of their treatments (Dr M. Guma, personal communication, December 2013). Such practices enhance the chance of STI/HIV infection.

Safer Sex Practices

Three main safer sex practices that are recommended to reduce the risk of STI/HIV infection and falling pregnant are (1) sexual abstinence, (2) avoiding multiple sexual partnerships, and (3) using condoms, both male and female types, correctly and consistently every time one has sex. However, this is easier said than done especially among those who have reached the age of consent within their specific cultures, as they are considered mature enough to have sex and the drive to have sexual intercourse is primordial. Many people find it very difficult to practice safe sex and consequently unsafe sexual practices occur quite frequently.

The only way to completely eliminate all these risks is to abstain entirely from sexual activity. Nevertheless, sexual abstinence is difficult especially for those who have attained the age of consent in any culture. Instead, delaying sexual debut remains an important focus for STI/HIV prevention, especially for adolescents. Some interventions that promote primary or secondary abstinence and delayed sexual debut can reduce an individual's risk of being exposed to STIs/HIV although their effectiveness remains doubtful (see Kantor et al., 2008; UNAIDS, 2013). Research has found that reasons for delaying early sex among young females tend to include religious injunction against premarital sex, prevention of HIV infection, fear of pregnancy, and linked to this, the fear of dropping out of school (Ankomah et al., 2011). These factors should be considered when developing STI/HIV prevention programs.

Reducing partner turnover and overall numbers of sexual partners is a key component of an effective STI/HIV prevention response (UNAIDS, 2013). The basic message is the promotion of fidelity to one sexual partner whose STI/HIV status is known. Programs are needed that discourage multiple sexual partnerships, or – where this is not possible – to emphasize the consistent use of condoms. In particular, it is critical to address the social norms, which sanction the involvement of males in multiple sexual partnerships. This issue needs to be taken up by whole communities and should not be left to individuals to be dealt with.

Condoms, both male and female, are currently the only available and most effective technology to prevent HIV and other STIs, as well as unintended pregnancies, among sexually active people (UNAIDS, 2013). Increasing the availability of female condoms (Guerra and Simbayi, 2014; UNAIDS, 2013) and promoting consistent condom use remain important focal areas for change. Male condoms are inexpensive, cost effective, their use does not require assistance of medical or healthcare personnel, and they can be utilized by anyone who is sexually active. Correct and consistent use of both male and female condoms is an integral component of combination HIV prevention strategies that individuals can choose at different times in their lives to reduce risks of sexual exposure to HIV and other STIs, or as a dual protective method.

In terms of sex work, ways of making sex safe for both sex workers and their clients is critical. This includes both improving the way they are treated by the law and improving their access to health care services, including the provision of, or access to, male and female condoms as well as lubricants (UNAIDS, 2013). Similarly, ways need to be found to encourage people to drink alcohol responsibly, especially if they intend to have sex. Recent work in South Africa has shown that multilevel interventions that target both men who drink in informal drinking places (or 'shebeens') and the surrounding communities may help reduce risks for STI/HIV infections (see Kalichman et al., in press).

Finally, as cultures continue to evolve it is imperative that cultural practices such as polygyny, dry sex, early marriage, cultural rites of death, and traditional healing practices involving sex with a client are reconsidered among those cultures that practice them in order to reduce the risk of STI/HIV infection and also unwanted pregnancies. This will require working closely with traditional leaders who are the custodians of culture in many societies the world over.

Conclusions

In this article we presented several sexual risk behaviors, which facilitate STI/HIV transmission through mixing of blood, sperm, and vaginal fluids between or among sexual partners. Some of these sexual practices also carry the risk of unwanted pregnancies. The article then discussed safer sex practices to prevent both STI/HIV infection and unwanted pregnancies. Recommendations were also made on how to also reduce the impact of sex work, alcohol, and culturally sanctioned sexual practices. It is hoped that the article has shed some light on the important issue of sexual risk behaviors and their health and social implications for both social and behavioral scientists and the public at large.

Sexuality and Social Work

Mark Henrickson, Massey University, Auckland, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Sexuality has been described as an umbrella term that relates to a private dimension of people's lives, but a number of social work authors propose that sexuality must also be understood in the cultural and sociopolitical contexts of cisgendered heteronormativity. Social work's core values include social justice, human rights, and the dignity and worth of the individual, and are well positioned to address these issues in practice, education, and research environments. This article introduces a taxonomy of sexuality and gender, briefly explores sociopolitical contexts that pose critical challenges to sexual and gender minorities, and considers social work responses to these challenges.

Introduction

Sexuality has been described as an umbrella term that "relates to the private dimension in which people live out their sexual, intimate and/or emotional desires" (Dunk-West and Hafford-Letchfield, 2011: p. 2). The place of sexuality within social work is contested. A number of social work authors propose that this private dimension must be understood in cultural and sociopolitical contexts as well as at the individual level. The interplay of these dimensions is reflected in the way sexuality has been treated in the social work literature.

In the social work literature, sexuality has usually been understood as having to do with gender and sexual minorities, people who identify (or who are labeled) with terms like gay, lesbian, bisexual, or transgender. Some social work authors have portrayed these sexualities as cultural variants, where the social work student and practitioner learn something about sexual and gender minorities and their needs in order to be more culturally competent in their practice (Mallon, 2008). More recently, this liberal notion has been critiqued by those who claim that such cultural models of social work education and practice are rooted in heterosexual understandings of the world, and do not take into account the fundamental issue of heteronormativity (Hicks, 2008), that is, the assumption that heterosexuality – opposite-sex attraction and desire, and the legal and social rights, institutions, and privileges that go with it, such as marriage and child rearing – is natural, inevitable, or desirable (Montgomery and Stewart, 2012: p. 164). Cultural variant approaches have also been criticized for problematizing sexual and gender minorities. Some social work authors have taken a pragmatic critical approach that comprises both of these perspectives (Cosis Brown and Cocker, 2011).

Although sexuality has been undertheorized in the social work literature (Fish, 2008), social work, as a discipline whose core values include social justice, human rights, and the dignity and worth of the individual, is well positioned to address these issues in practice and policy, academic and research environments. This article introduces a taxonomy of sexuality and gender, encourages looking beyond Western biases of contemporary sexual and gender identity discourse, and briefly explores some sociopolitical contexts that pose critical challenges to sexual and gender minorities. Finally, some social work responses to these challenges will be considered.

Taxonomy

The taxonomy of sexuality and gender is complex. It draws on the psychological, political, and social work literature, as well as the growing interdisciplinary and international literature of queer theory. A full exploration of essentialist and social constructionist approaches to sexual identity (see Hammack, 2005) is beyond the scope of this article, but understanding the debate is helpful in understanding the development of sexual and gender identity theories. In brief, an essentialist position posits that individuals are born with a sexual identity, such as hetero- or homosexual, and that a major developmental task for such individuals is to discover and claim that essential identity. Social constructionist theories posit that sexual identities are largely constructed by their social and cultural contexts, and that people construct their identities in conformity to those contexts.

In the last few decades, the life course perspective that integrates these two approaches has emerged. Concepts such as heterosexual, homosexual, bisexual, and even male, female, and transgender may seem to be obvious at first glance, and in everyday use their meanings may seem clear. But there are a number of problems with these commonly used words. These apparently simple words refer to complex categories that comprise biology (DNA), anatomy (the so-called reproductive organs and secondary sexual characteristics), behaviors (who we have sexual activity with), attractions (who we are sexually attracted to), emotions (who we fall in love with), and fantasies (daydreams and night dreams). These words have often been used in ways that assume that these different attributes are aligned with each other, and are static and unchanging throughout our lives. Drawing on interdisciplinary research we now understand that people's identities are not static and that they can evolve and change over the course of their lives. The life course perspective of human development (Hammack and Cohler, 2009) proposes that biological desire motivates behavior, and individuals "internalize the sexual story possibilities" (Hammack, 2005: p. 281) of a culture in order to create lived identities. Individuals not only recognize their essential desires but also learn cultural stories to construct their evolving identities.

Challenging Binaries

The words male and female carry with them the assumption that people's genders are binary, that is, that people are either

one or the other. This notion is challenged by social work transgender theorists (Teich, 2012; Alleyn and Jones, 2010; Markman, 2011), who propose that sex (that is, biology and anatomy), gender identity (the individual experience of femaleness and maleness), and gender expression (behavior) can best be expressed as continua, rather than as discrete binaries. Some people experience themselves as gender syntonic, or cisgendered, that is, their experience of their gender matches the biological sex with which they were labeled at birth (Teich, 2012: p. 15), and some people experience themselves as gender dysphoric, gender dissonant, transgendered, or transsexual, that is, they do not identify with the sex to which they were assigned at birth. Some people are born with unambiguous sexual characteristics, and others are born with ambiguous sexual characteristics (Cornnwall, 2010), some of whom identify as intersex, or 'gender fluid' (Solomon, 2012: p. 602). Transgendered, intersexed, and gender fluid people may or may not choose consistently to present or express themselves publicly as male or female, and may or may not choose to modify their bodies with hormones, transformation surgery, or other means.

In the same way that gender is now becoming understood as a continuum, so also sexual behavior, attraction, emotion, and fantasy are also more appropriately understood as continua. The venerable Kinsey studies (Kinsey et al., 1948, 1953) introduced this idea in the mid-twentieth century, and in a more evolved form, this continuum concept is increasingly supported by research, particularly in women (Diamond, 2005; Hines, 2012; Rosario et al., 2006). For social workers to assume that a client who presents to the social worker as partnered to someone of the opposite sex is sexually active only with that partner, or only with others of that partner's sex, or to assume that the sexual (or even gender) identity of a long-term client will remain unchanged over time is to risk overlooking a significant part of the ecology of the client.

Sexual or gender minority individuals will probably experience themselves as different in some fundamental ways from their birth parents, and will in all likelihood develop an epistemological framework to understand that difference: they will quickly learn to question what they are told about people like themselves, and to validate knowledge primarily through their own experiences, rather than through what they are told by others. They will learn to reject the vertical identity provided by affiliation with their parents or caregivers and develop more horizontal identities (Solomon, 2012). Another salient feature of a sexual or gender minority epistemology is the decision to disclose. Most sexual or gender minorities cannot be identified by the casual observer by any outward appearance or presentation: they must choose to disclose, either by a verbal statement or in some other obvious way in each new environment, with each new person. That sexual and gender minorities must make a decision to disaffiliate with a cisgendered heteronormative world also shapes the way these individuals interact in the world. If a sexual minority client sits down in an agency waiting area and sees only family-life magazines, or overhears remarks about heteronormative family life from administrative staff, then the agency has established a heteronormative environment, and the responsibility to disclose a nonconforming identity now falls to the client.

A Global Context

Notions of individual sexual identities are largely perceived as Western constructs, where sexual identity becomes the entire or primary identity of the individual, rather than a matrix of intersecting social identities such as culture, tribe, or other social status. Social workers should not assume that these sexuality constructs are globally shared. In the Asia–Pacific context, for example, there is a multifarious array of social and cultural roles, behaviors, identities, and sexual and gender expressions that are quite different from Western-style lesbian, gay, bisexual, and transgender individual identities (Lim, 2008; Peletz, 2009; Murray, 2002). Yet, in multinational urban areas like Hong Kong or Singapore, Western-style sexual identities also exist (Martin et al., 2008). Similar observations can be made about other parts of the world (Whitaker, 2006; Murray and Roscoe, 1998). One challenge to local cultural and indigenous expressions of identity is the Internet, where English and its hegemonic Western identity constructs have been the dominant language. In an increasingly migrant world, social workers who use only Western constructs will miss key nuances to individual identities. The language of 'queer' by sexual and gender minorities is being reclaimed as an insider term, a "destabilizing rebellion against the formation of identities around fixed poles of gender or sexual orientation" (Shernoff, 2008: p. 143).

Heterosexual Privilege

The most significant critique of the prevailing social work taxonomy of sexual and gender minorities is that these notions are othering (Dominelli, 2002: p. 18) and exclusive. Such terms indicate putative cisgendered heterosexual power over sexual and gender minorities to name, objectify, pathologize, and confer privilege on cisgendered heterosexuality as both normal and normative. When social workers use words like lesbian, gay, or transgendered, they may be reproducing those categories, and thereby identifying them as inferior (Fish, 2008). A position of heteronormativity is thereby adopted from which to know about sexual and gender minorities as objects of knowledge. Thus, heteronormativity and heterosexuality remain unexamined and invisible (Hicks, 2008: p. 68), as well as privileged.

It is for these reasons that social workers, particularly those who work in multicultural environments, will wish to avoid objectifying language such as lesbian, gay, and bisexual: this vocabulary is not universally meaningful. In addition, lengthy and reductionist acronyms (e.g., LGBTIQQ) that attempt to be inclusive inevitably omit some possible identities, particularly indigenous cultural identities. How many heterosexuals would respond well to being labeled 'Het' in a social work text or client record? The language 'sexual and gender minorities' may be the most inclusive language, and can readily be used in practice and research until individuals and communities indicate which terms they prefer to use about themselves.

Sociopolitical Contexts: Sexuality and Human Rights

Sexuality must be understood in sociopolitical contexts. For social work, this also means that sexuality must be understood with a view to the fundamental social work principles of social

justice, human rights, and the dignity and worth of persons (International Federation of Social Workers, 2004). Human immunodeficiency virus (HIV), the increasing visibility of sexual and gender minorities, and the current debate about legal recognition of same-sex relationships have brought into sharp relief the statutory situations of sexual and gender minorities around the world. Although there have been significant gains in many countries and jurisdictions, the enduring existence of sexual and gender minorities in cultures and countries around the world does not by any means imply universal acceptance or even tolerance. Uncritical assumptions about what is normal has social, criminal, and too often fatal consequences for sexual and gender minorities – the ultimate expression of heterosexual privilege and dominance. The late lesbian writer Adrienne Rich argued that "heterosexuality has had to be imposed, managed, organized, propagandized and maintained by force" (1983, cited in Fish, 2008: p. 188).

State-Enforced Conformity

There are a number of countries in the world where consensual adult same-sex relationships are punishable by whipping (e.g., Malaysia), imprisonment (e.g., Myanmar/Burma, Tanzania, Uganda), torture (e.g., Uganda), or death (e.g., Iran, Mauritania, Qatar, Saudi Arabia, Sudan, Yemen, and parts of Nigeria) (Amnesty International, 2008). Although homosexuality is a capital crime in Iran, Iran has a liberal approach to transsexuality; Iran has the second highest rate of gender reassignment surgery in the world (after Thailand). Transsexuality is constructed as a medical condition and the state provides up to half the cost of transformation surgery. This means that many sexual minorities are pressured to undertake gender reassignment surgery to live their identities (Najmabadi, 2011). In 2007, Kuwait enacted a law that made it a criminal offense 'to imitate the appearance of the opposite sex' (Amnesty International, 2008: p. 12). Although the High Court of Delhi (India) declared unconstitutional Section 377 of its 1861 Penal Code, a legacy of the British Raj, which criminalized 'voluntary carnal intercourse against the order of nature' (Peletz, 2009), that decision was itself overturned by the Indian Supreme Court in December 2013.

In November 2012, the Uganda Parliament revived its infamous 'Kill the gays' bill (as it was known; Okeowo, 2012); in February 2013, Ugandan President Musevini signed a version of the law that criminalized same-sex sexual activity for both men and women with penalties ranging to life in prison, although it did not include the death penalty. This action followed similar legislation in Nigeria enacted in January 2014.

It is not that only sexual behaviors or appearances have drawn the attention of legislators. Although homosexuality was decriminalized in Russia in 1993, the Russian Duma passed a law in June 2013, which criminalized providing information about homosexuality to people under the age of 18 years. This law was the focus of much protest associated with the 2014 Winter Olympics in Sochi, Russia.

In some countries and regions, social workers and social work organizations have chosen to speak out against such political and cultural oppression and violence. In others, they have supported oppressive laws. In yet others, they have been forced, or have strategically chosen, to remain silent.

Socially Enforced Conformity

Even where oppressive statutes are not enforced, or where laws are enlightened, climates of public intolerance and fear can be created. South Africa is the first country in the world to offer sexual minorities equal protection in its constitution, but this protection does not stop political leaders from referring to sexual minority communities in stigmatizing language (Francis and Msibi, 2011: p. 162). South African lesbians as well as transgender men and heterosexual women who 'defy traditional roles' have lived in fear of so-called corrective rape and murder because the victims 'do not conform to a stereotype heteronormative gender role' (Bavoso, 2012). Reports of corrective rape have also come from Uganda (Okeowo, 2012).

HIV

There can be no doubt that one of the most significant influences on the contemporary history of sexual and gender minorities, particularly among men who have sex with men (MSM), has been HIV. The acquired immunodeficiency syndrome pandemic in developed nations was first identified among MSM in the late 1970s (then called GRID). In most developed nations, sexual and gender minority communities led the way in community organizing prevention through education, political advocacy, and a caring and compassionate response to people whose lives were irrevocably altered or ended by HIV. Social workers and social work researchers – particularly sexual and gender minority social workers – have contributed extensively to the global responses to HIV. Just as HIV spurred a massive global pharmacotherapeutic research effort with flow-on effects to other conditions, and served as a model for advocacy and policies in people affected by other chronic conditions, so it also spurred global social work research into areas such as effective prevention education models, treatment adherence, care and management, a reconceptualization of family and care, and the effects of stigma, which have had enduring benefits.

Religion

Another area where sexuality and gender are frequently contested is religion. Social workers are often anxious about trespassing into the domain of religions. Yet social workers are often members of religious groups and are informed by religious values systems (Cosis Brown and Cocker, 2011). Certainly, gender and sexual minorities are affected by religious values, both directly when they are included or excluded, and indirectly, as other people read about experiences of inclusion or exclusion. Religious organizations may use texts or traditions to establish boundaries about what is acceptable or tolerable behavior around individuals or groups (Henrickson, 2009). Faith-based discrimination, exclusion, and disgust are inappropriate in any setting, and are particularly inappropriate in a social worker. Wilton has written that "in cases where [faith] comes into conflict with a practitioner's ability to deliver respectful and appropriate care, there is a clear obligation to prioritize professional standards over personal belief or morality" (Wilton, 2000, cited in Cosis Brown and Cocker, 2011: p. 91). Attitudes such as 'I do not approve of their lifestyle but I would still work with them' are equally inappropriate, for it is unlikely that a sexual or gender minority individual would want to work with someone with

such judgments. Claims by social workers that they have a right to judgmental views justified by religion and that their views are not being respected have been addressed (Melendez and LaSala, 2006). Social workers can promote social justice approaches by providing assistance in developing advocacy, providing informed testimony and other support for decision-making processes within religious bodies, and assisting affected individuals to find alternative support or safety when it is clear that a particular religious body is actively unsafe. While in many places religious bodies are not governed by laws of the state, they are not immune to public opinion, and all religions have evolved their beliefs, theologies, and practices over time.

A Social Work Response

Antioppressive practice (Dominelli, 2002; Baines, 2011) and the companion discourse of antidiscriminatory practice have been the most frequently utilized theoretical and practice social work responses in the domain of sexuality (Hines, 2012). Brown has proposed, however, that antidiscriminatory discourse "has had very little to offer lesbians and gay men" (2008, as cited in Cocker and Hafford-Letchfield, 2010: p. 2002). Antioppressive practice appears ideally suited to challenge the power inequalities that exist between cisgendered heteronormative majorities and sexual and gender minorities. However, a critique of antioppressive practice is that it often places sexuality within a matrix of structural oppressions, such as racism, sexism, ageism, ableism, and classism (Massaquoi, 2011), and in these matrices, sexuality is often ranked low, hidden, or ignored. We have seen that labeling sexual and gender minorities is an act of othering that can itself be constructed as oppressive. Antioppressive practice as usually interpreted, then, may be a necessary but of itself insufficient response for social work in the domain of sexuality.

Social workers must critically examine their assumptions about heteronormativity, and interrogate those assumptions and their othering vocabulary, so that social work practice, education, and research do not replicate or reinforce heteronorms and privileges. This reflexive and liberating approach appropriately problematizes groups and individuals who exclude, rather than those who are excluded, and places responsibility for restoring equity and justice on sexual and gender majorities, rather than exclusively on sexual and gender minorities. Such an approach may mean that in an academic environment, where sexuality issues are not adequately included, cisgendered heterosexual teachers carry the responsibility for initiating discussions about heterosexual privilege in the same way that culturally dominant groups carry responsibility for initiating discussions about racism. Such proactive approaches are not only entirely consistent with, but are also arguably required by the shared code of ethics of the international social work organizations. These approaches also encourage critical self-examination that will liberate cisgendered heterosexual social work educators, practitioners, and researchers from roles, behaviors, attitudes, and assumptions that confine them.

Practice

Cocker and Hafford-Letchfield (2010: p. 2004) ask whether it is possible for social work to deliver an equitable service for lesbians and gay men. Their response is that there is work to do, and that this work must begin by improving partnerships in service delivery and research, and by transferring power from professionals to service users and their communities. As we have seen, social workers in all areas of practice have been largely informed by the discourses that problematize sexuality, where sexual identity is seen as the problem rather than the heteronormative environment in which the sexual or gender minority individual lives (Hicks, 2008). Child protection practitioners must engage even young children about their self-understandings, for sexual and gender minority children may experience themselves as different even when they may not have a language for that difference. To place a sexual or gender minority child with carers who are unwilling or unable to support that child's growing awareness of difference will put that child at as much risk as any other violence. Assessing same sex couples for suitability for foster care or adoption should focus not merely on the same-sex part of the relationship, but also on the overall suitability of the candidates.

Other practice areas present particular issues:

- In schools, sexual and gender minority children are at risk of bullying; even where the individual is not a member of a sexual or gender minority, the perception of membership may present sufficient risk. Antibullying interventions benefit all young people.
- Sexual and gender minorities face a unique constellation of challenges in health, mental health, and substance misuse settings, including increased risk of self-harm (D'Augelli and Patterson, 2001). The use of so-called reparative therapy, which attempts to change the orientations of sexual minority individuals, is highly disputed (Grace, 2006; Becksted, 2012), and has been called unethical (Bright, 2004).
- Social work with transgendered individuals in prisons and domestic violence shelters present particular challenges, but steps must be taken to ensure the safety and well-being of both transgender and nontrans people (Teich, 2012).
- Social workers in migrant and refugee settings must be mindful of legal and social restrictions about sexual and gender minorities in sending countries; stigmatized identities will likely have been concealed. Alternatively, some individuals may claim refugee status based on the way sexual and gender minorities or people perceived to be at risk for HIV are criminalized or in danger in their home countries.
- Aging individuals who are members of sexual or gender minorities demonstrate particular resilience and satisfaction compared to aging heterosexuals (Henrickson and Neville, 2012); nevertheless social workers in aged care settings should be mindful of the different social needs of different aging communities.
- Individuals who have multiple minoritized statuses should be supported to express their identities in ways that include and integrate all aspects of their identities (Henrickson, 2006).
- Social workers in policy-making settings who are working to establish legal and social equality for sexual and gender minorities will want to be mindful of the recent debate about 'homonormativity', an approach where the "resolution of the 'problem' of homosexuality is found through gradual legal and civil changes resulting in assimilation" (Hicks, 2008: p. 68). In many instances, gay and lesbian

rights groups adopt this gradualist model of change, even though it does not radically contest the foundations on which cisgendered heterosexual privileges are constructed.

Practice example 1: Mr Tomacelli is 81 years old and has been living in an aged care facility for the last 6 years. His only visitor has been his 50-year-old son, Paul, who has recently had to move further away, and can now visit only occasionally. At admission, Bob, the intake social worker, asked Mr Tomacelli if he was married or single. He responded that he had been married. He also said that his partner had died nearly 20 years ago, but they had raised a child together. Bob recorded that Mr Tomacelli was a widower with one child. Lately Mr Tomacelli has appeared withdrawn and depressed; he does not engage with other residents, and does not participate in any of the activities offered at the facility. He avoids Bob. Terry, another social worker at the facility, has informally engaged with Mr Tomacelli. Eventually, Mr Tomacelli discloses to Terry that he married young, and divorced after a few years. His life partner of nearly 25 years was Alessandro, who died almost 20 years ago. Mr Tomacelli and Alessandro raised Alessandro's son Paul together. The twentieth anniversary of Alessandro's death is approaching, and now that Paul has moved away, Mr Tomacelli has no one in his life with whom to share this important anniversary. Because homosexuality was illegal for most of Mr Tomacelli's life. He does not talk with strangers about his relationship with Alessandro, and does not consider himself gay. At this stage of his life, he is extremely lonely, and has only his memories. During the intake interview, Bob should not have worked from a heteronormative assumption that Mr Tomacelli had only one partner, or that the partner was female. Bob could have asked an open question about relationships in Mr Tomacelli's life, or invited him to talk about the important people in his life. Bob could have understood that an intake interview may need to extend over time, particularly as sexual minorities need time to assess whether individuals are trustworthy. Even if Bob had thought to ask, "Are you gay?", Mr Tomacelli would have denied it, since he does not use this language about himself. The responsibility fell to Mr Tomacelli to disclose, and since he did not know Bob, he did not do so. Terry's more informal engagement allowed Mr Tomacelli the time to assess how Terry might react to his disclosure, to share more about his life, to talk about the key people in his life, and how much they meant to him.

Practice example 2: Aliyah arrived in the country as a refugee a few weeks ago. She had been living in a designated refugee camp for 2 years following her escape from her village. The rebels had killed all of her family, raped her, and left her for dead. She saw her survival as both a blessing and a curse, but was able to make her way to an internationally protected safe area. Now, 2 years later, she has been relocated to a new country. The experienced social worker at the refugee support agency had read the official record and was extremely sympathetic about the trauma Aliyah had endured, but it was clear that she was not telling her whole story. Over time the social worker expressed only support, and gradually gained Aliyah's trust. Eventually she was able to tell the story of the massacre in her village: not only were her parents and extended kin killed, but also her children, and her female partner. None of her family knew about Aliyah's partner, but she suspects that her partner's brother may have betrayed them to the rebels. She now has great difficulty in trusting anyone. However, after her disclosure, the social worker helped Aliyah to make contact with a local support network for sexual minority women. The social worker's nonjudgmental attitude, support, and openness to hearing all of Aliyah's story gave her the confidence to share more of her story. Now Aliyah has the choice to access appropriate support for all aspects of her life, and not just the obvious traumas that she has experienced. The word lesbian has no meaning for Aliyah. She has been in relationships with both men and women, although at the time of the massacre, her primary emotional relationship was with her female partner.

Education

We know that education is effective in changing social work student attitudes about sexual minorities, and a number of authors have described their experiences offering courses and curricular content about heterosexism and sexual and gender minorities (Chonody et al., 2009; Francis and Msibi, 2011). Using an approach that problematizes heteronormative privilege rather than sexual or gender identities, sexual and gender minority individuals are not forced to disclose their identities in environments that may not be safe: although there is support for the approach that coming out in the classroom is a necessity for the sexual minority social work educator, there is also recognition that there is risk to openly disclosing educators, including lower student confidence, student perceptions that the lecturer is of poorer character, and lower credibility than heterosexual colleagues (Gates, 2011).

Sexual and gender minority students, even those who perform well, may arrive in the classroom with a history of experiences of harassment, discrimination, and even violence. Social work educators will need to make explicit statements to all students about their inclusion of sexual and gender minorities. Although it risks perpetuating the discourse of sexual and gender minority as a cultural other, Van Den Bergh and Crisp (2004) set out a useful attitudes, knowledge, and skills heuristic for social work education. Such content should be consistent across social work educational programs within a country, and assessed by professional regulatory bodies. An open attitude and the creation of safe spaces can be expressed in lectures, case presentations, case examples, classroom discussions, and examinations. Field education settings should be assessed to ensure that they are safe for sexual and gender minority students, and where necessary field supervisors should be upskilled, or alternative sites found.

Research

Jeyasingham (2008) advocates for more scholarship that identifies the ways day to day practice and social apparatuses operate to reinforce homophobia in social work contexts. Meezan and Martin (2009) have published an accessible and useful guide to research with sexual and gender minorities. As in practice, improving partnerships in research, transferring power from professionals to research participants and their communities, and avoiding othering language will benefit not only communities, but also social work theory building.

Conclusion

Sexuality inheres within all social work practice areas. Because of its core ethical principles, social work is well positioned to interrogate assumptions that identity is binary, stable, and fixed, and to challenge vocabularies of othering; to avoid uncritical assumptions about what is normal; and to oppose oppressive and lethal state policies and practices. Social workers must not problematize any minoritized identities but instead uphold core social work principles such as social justice, human rights, and the dignity and worth of the individual. Social work practitioners, educators, and researchers can and must take up the

possibly painful and difficult risk of critical self-examination and become aware of places where they, their colleagues, and students participate in the oppression of sexual and gender minorities, including where they are agents of oppressive or exclusive state policies. Social workers in all practice areas must become aware of cisgendered heterosexual privilege and the way that privilege supports existing oppression and exclusion, and maintains hegemony over sexual and gender minorities.

Sexuality and Space

Abstract

Sexuality and space are mutually constituted – space makes sexuality and sexuality makes space. Sexuality – as with other identity categories like gender and race – is not fixed or static, but shifts and changes depending upon politics, place, and space. Sexuality and space scholarship can be found in social, cultural, feminist, and queer geographical subdisciplines. This scholarship questions the ways in which sexual identities conform to, and/or resist, certain societal norms. Attention to the intersections of sexual identities with other identities – such as gender, race/ethnicity, age, and (dis)ability – highlights current and ongoing debates in studies of sexuality and space.

Sexuality and space are mutually constituted – space makes sexuality and sexuality makes space. Sexuality – as with other identity categories like gender and race – is not fixed or static, yet is constantly shifting across various cultural and social landscapes. Sexuality and space are also highly contested and the ways in which we live out body/place relationships are political. Over the last three decades geographers have recognized that the body is a politicized site of contestation, struggle, and possibilities. The materiality of bodies is both fluid and fixed, constricted and freed by gender, sex, sexuality, race, class nationality, and disability. In other words, our understanding of sexuality, sexed bodies, and sexual identities is socially crafted, *and* laden with knowledge and politics that are particular to time and place.

Studies of sexuality and space map, connect, and integrate sexed bodies not just through the most obviously sexed public spaces such as bars, casinos, and city red light districts, but also through all spaces. Think, for example, about sexuality and the space of homes (Morrison, 2012). Homes are sites of a range of variety of sexual relations. Nuclear families, extended families, gay and lesbian homes, polyamorous homes, and young people living together are just a few examples of sexual relations that are constituted within intimate and often private home spaces. Whether it is a bar, casino, red light district, or a home sexual politics permeate space. Equally, there are no spaces that sit outside of sexual politics. Sex, space, and politics cannot be disentangled, and geographers have been unraveling some of the complexity and diversity that constructs the embodied experiences of sex and sexuality.

It is not just 'real' or material space that matters to sexed bodies; virtual spaces are equally significant to constructions of sexuality. There are millions of web sites on every kind of sexual identity and sexual performance, for example, pornography, romance, 'find a bride', gay, lesbian, bisexual, and transgendered web sites. Online social media, such as Facebook, is another example of virtual space providing new opportunities for sexual identities, connections, interactions, and communities to emerge. Virtual spaces may enable people to try out new sexual identities unrestricted by the limitations of their real bodies. As technology continues to develop, new levels of communication in nonphysical connections between people are enhanced. Erotic connections are formed and people engage in sexual intimacies, get married, have affairs, and so on, all online.

In what follows I first outline some of the earliest scholarship on sexuality and space. These informal beginnings sparked a deep interest in identity, place, and power. Second, attention is turned to the influence that feminist and queer theories have had on sexuality and space research. During this period, geographers in particular began to question the ways in which heterosexual and homosexual identities conformed to certain societal norms. Finally, the intersections of sexual identities with other identities – such as gender, race/ethnicity, age, and (dis)ability – are offered by way of highlighting current and ongoing debates in studies of sexuality and space.

Geographies of Sexualities: Beginnings

Scholarship on sexuality and space started to appear in the late 1970s. Geographers interested in pursuing this research agenda tended to meet informally because sexuality was deemed not to be a topic that geographers should engage in, but by the end of the 1970s some publications could be found. By the 1980s – when positivism started to lose its grip on the discipline – more sexuality and space studies emerged (Lauria and Knopp, 1985). The 1980s is perhaps best known for the period in which the intersections of class and gay identity dominated scholarship as studies considered the role of gay men and gentrification in US cities (Lauria and Knopp, 1985).

The first lesbian urban geography scholarship appeared in the early 1990s and this period is particularly notable for the groundbreaking research by Gill Valentine (1993). Also significant during the 1990s were the number of studies that discussed topics such as 'eroticized topographies' and sexual identities (Bell, 1994). Much of the 1990s literature on space and sexuality was collected together in one volume – David Bell and Gill Valentine's *Mapping Desire* (1995) – that included topics such as sexualized landscapes, homes, suburbs, lesbian neighborhoods, red light districts, rural spaces, Jamaican ragga, and gay resistance, to name just a few examples. This was a period of scholarship in which it was asserted that sexual politics permeate all space – private and public, urban and rural, at the macro and micro level. Notably, these studies show the desire to draw on feminist, poststructural, and queer

theories in order to examine 'difference.' Many of these studies challenged the notion of fixed identities and spaces by focusing on the proliferation of identities, rather than structural inequalities. Bell and Valentine (1995: 4) frame this early work by noting:

> The women's, gay and civil rights movements emerged in North America and Europe in the 1960s and 1970s on a wave of social and political upheaval. But despite a growing awareness amongst geographers in the following decade of the need to study the role of class, gender and ethnicity in shaping social, cultural and economic geographies, sexualities were largely left off the geographical map.

Bell and Valentine's edited collection was vitally important in helping put sexuality on the geographical map. This collection is known for its empirically rich case studies and less for its advancement of sexuality theories. It opened up, however, pathways for scholars to focus on spatial theories of desire. During the mid-1990s queer politics and activism emerged when numerous governments failed to respond adequately to the AIDS crisis (particularly in the United Kingdom and the United States). New forms of queer activism emerged in order to raise awareness and support for people with AIDS. Geographers have made effective use of both queer politics and queer theory to further understand the performance of sexed bodies and sexual identities in space.

It is not surprising that this early work reflects a disparity between theory and empirics as it reflects the ways in which knowledge and power intersect. Notably geographers have been slow to question taken-for-granted sexualities, such as heterosexuality. The pioneering scholarship of Adrienne Rich's (1980) and her focus on 'compulsory heterosexuality' has been picked up by some geographers who have been able to show the ways in which most people unconsciously use heterosexuality to structure their lived everyday spaces. The socially constructed 'naturalness' of heterosexuality is produced at a variety of scales: babies are expected to be born male or female (not all are); girls and boys (in modern industrial contexts) are expected to grow up to be mothers and fathers and create nuclear households; and a set of prescribed gender norms are attached to these heterosexual roles (Butler, 1990). This normalizing of heterosexuality is also incorporated into the spaces of geographical disciplines which means heteronormativity pervades the ways in which geographers investigate place and space (Rose, 1993). Some have charted the ways in which heterosexism pervades the institutional practices of geography (and creates heterosexist scholarship (Binnie, 1997; Rose, 1993)). Overall, these scholars argue that heterosexism underpins geographical notions of self, place, gender, and sexuality. Hence, the 1990s can be recognized as a period of sexuality and space scholarship which is noted for the critiques of studies that reproduced hegemonic versions of heterosexuality – including family life – and made these studies appear natural, legitimate, innocent, and even morally right.

The term 'heteronormative' is now a widely used concept. Gayle Rubin (1993) was one of the first feminists to first use the concept, and since then geographers, such as Hubbard (2008: 643), have researched places and spaces that are inscribed by 'a normative heterosexuality, in which it is assumed individuals' sexual identities conform to a social norm of heterosexual love, sex, and reproduction'. Heterosexual norms are constructed and reproduced in almost every space and place. Some heterosexualities are considered deviant (for example, sex workers), while others are valorized and held up as exemplar identities that are enshrined in biological discourses (for example, husband and wife couples).

The work of Heidi Nast (1998) is influential here, as she shows how heteronormativity can be found within an array of everyday geographies from the body to the globe. She draws on modern nationalist discourses – languages and imagery – to show the ways in which nation states depend on a type of pure representation of the maternal and of nuclear families. Some nation states are represented using phallic imagery and language that glorify the Oedipal nuclear family father while other nation states represent their territory using images and language of the maternal. Furthermore, in the context of industrial interests the nuclear family is promoted as the core setting for reproducing and socializing industrial workers.

A great deal of discussion has also addressed the notion of 'homonormativity.' It has been adopted to show how certain performances of homosexuality incorporate the logic of heteronormativity. Becoming a normative homosexual usually means gaining the privileges associated with neoliberal politics and practices that are aligned with heterosexuality and class privileges (Browne et al., 2007). Such practices produce a new 'homonormative' identity, which gains popularity as more radical performances of homosexuality become marginalized. 'Acceptable' gay public spheres shrink and typically become defined as consumption spaces and gentrified neighborhoods. A new kind of normativity is emerging as countries around the world debate whether to change laws so that all people, regardless of sex, sexual orientation, or gender identity will have the opportunity to marry if they so choose. These public debates are often centered on the ways in which religious institutions regulate normative sexualities. The concern is that marriage becomes the defining relationship upon which access to social justice and forms of belonging are then measured. These state legislated couple normalities need to be questioned using queer theories.

Queer Spaces, Circuits, and Fields: Questioning Normativities

The turn to queer geographies (Binnie, 1997) is, in part, a reaction against heterosexist geographies, but also an opportunity to distance the subfield of sexuality and space from feminist geography. Queer geographies, however, have benefited from feminist geographers' critical engagement with gender and sexuality. Feminist geographers have been quick to question the authority assigned to science and 'objective' claims of 'universal truth.' A very good example of the use of queer theories by feminist geographers is the work of Gibson-Graham (1996). In the article 'Querying Globalization' Gibson-Graham (1996) draw on feminist theorizations of sexual identities to upset the naturalness and legitimacy of global capitalism. They bring together Marxian theoretical constructions of capital and rape discourses that construct women as victims. Marxian theories often script capitalism as

violently irrepressible, and as discourse 'capitalism' gathers strength from heterosexualized language. Gibson–Graham (1996: 146) attempt to make "globalization less genital, less phallic, by highlighting various points of excess in its inscriptions – places where the inscription can be seen as uncontrollable or indeterminate, or as potentially inscribing noncapitalist identity."

Sexuality has a profound effect on the way people live in, and interact with, space and place. In turn, space and place affect people's sexuality. Gill Valentine (2001: 5) offers an example of the way place and sexuality are mutually constituted, explaining:

> Spatial visibility (e.g., in terms of the establishment of so-called gay ghettos or various forms of street protest or Mardi Gras) has been important to the development of lesbian and gay rights. In turn, these performances of sexual dissidents' identities (re)produce these spaces as lesbian and gay spaces in which sexual identities can be, and are forged.

What Valentine's example makes clear is that space and sexuality do not just interact with, or reflect, each other but rather are mutually constituted. Geographers have noted that place matters – where one is located, what language is being used, and the privileges or lack of – to the production of sexuality and space scholarship. For example, sexuality and space knowledge is different 'down under' in Aotearoa, New Zealand, and Australia to that produced elsewhere.

Queer geographies question the relationships between gender, sex, and sexuality and assert that we have multiple genders and sexualities. At the core of this scholarship is the understanding of sexuality as a social process that allows for expressions of desire (in all directions and beyond dichotomizing discourses). Queer geographers have become dissatisfied with essentializing, limiting, neoliberal, and often Westernized sexual categories. They have turned to fluid, unstable, and ambiguous conceptualizations of sexualities. Spaces, like sexualities, are also considered fluid and ambiguous. This is a move away from "reified phenomena such as 'gay gentrification' and 'gay neighborhoods' (which also tended to be celebrated) to understanding more fluid, ambiguous and contingently sexualized spatialities such as circuits and fields" (Knopp, 2007: 49).

Many articles on sexuality and space are sprinkled throughout a variety of social, cultural, and feminist geography literature. For example, studies such as 'the closet' (Brown, 2000), which is used as both a metaphor but also as a 'spatial practice of power-knowledge' that takes up the notion of spatial scale. The body, city, nation, and globe are spaces in which the closet may be a place of creative and transformative sexual and political resistance to heteronormativity (Brown, 2000).

There are also a number of edited (e.g., Browne et al., 2007) and authored books (e.g., Johnston and Longhurst, 2010; Hubbard, 2011) on the topic of sexuality and space. Topics explored in this literature include the pink economy, gay tourism, gay pride parades, bisexuality, sexuality in rural areas, sexuality and the city, sexuality and citizenship, the globalization of sexuality, HIV and AIDS, and sexuality and ethnicity.

In Browne et al.'s (2007) edited collection *Geographies of Sexualities*: *Theories*, *Practices and Politics*, they say 'geographies of sexualities' is a young field but has 'blossomed' over the past 10 years. It is an area that is now taught in a number of undergraduate courses, at least in countries such as the United Kingdom, the United States, Canada, Australia, and New Zealand, and has succeeded in striking up conversations with a range of other subdisciplinary areas such as cultural and social geography, gender studies, migration studies, and tourism. It's important to note that sexuality and space is not a discrete intellectual field but one that has emerged through its relation with other disciplinary areas.

Sexuality and Other Identities: Queerer Possibilities

In a recent review of sexuality and space, Michael Brown (2012) notes a number of 'intersectional anxieties' that are worth raising as a way of charting future research. He turns his attention to the ways in which sexuality and space studies have (and have not) intersected with other axis of identity, such as gender, race, class, age, (dis)ability, and religion. A consensus is building that if studies of sexualities and space are to be truly queer, then they cannot focus solely on sexuality; rather, connections with other social identities must be considered (see Oswin, 2004). This kind of critique has been leveled at queer theories and activism (Browne et al., 2007).

Geographers stress, not surprisingly, how place brings different identities together (see Peake, 2010 for an account of the intersections of sexuality and race). Geographers have begun to take seriously the notion of intersectionality. The concept of intersectionality can be traced back to the early 1990s in feminist legal scholarship. Kimberle Crenshaw's (1991) article 'Mapping the margins: intersectionality, identity politics and violence against women of color' highlighted the ways in which a black woman is oppressed by both racism *and* patriarchy in ways that black men are not. She argued further that the danger of focusing on a one-dimensional identity and experiences of inequality associated with that one identity – meant researchers risk marginalizing other identities and hence erasing the ways in which people become positioned differently from one another. Crenshaw (1991), therefore, urged researchers to pay attention to the specificities of experienced oppressions.

Some geographers (Olund, 2010) reject Crenshaw's early argument of intersectionality because of the tendency to think of identities as separate (rather than enmeshed) and hence, ironically, essentializing. Using the term 'anticategorical intersectionality', it is argued that the metaphor of intersection is premised on an empirical or conceptual separation of two identities.

So how has sexuality intersected with other identities to produce different spaces? Brown (2012) notes that most scholarship looks at the importance of place in bringing different identities together and less research has been done looking at the convergence of identities across spaces. The scholarship that does exist is uneven.

One of the most researched intersections is sex, gender, and place. A number of studies group together lesbians and gays as single populations (Mulligan, 2008; Waitt, 2005). Also

prominent is work on sexuality and space that separates lesbians (Holmes, 2009; Johnston, 2007; Podmore, 2006) and gay men (Waitt, 2005) at a variety of spatial scales, from bodies and homes to communities, institutions, nations, and the globe.

After many cries for critical scholarship on heterosexuality and space, there are now publications that attend to the intersection of genders and heterosexual identities (Hubbard, 2008; Morrison, 2012). Some have focused on the ways in which particular women may be disciplined and controlled in heteronormative and patriarchal ways, and attention to heterosexual men is a recent trend. New and changing forms of masculine heterosexuality can be found in lifestyle magazines, for example, where sexual prowess is a key component of contemporary masculine identities. It is notable that some towns and cities appear to encourage sexualized rituals more easily than others. Newcastle in England, for example, has a reputation as a party city and is a site that is associated with excessive drinking, wild stag, and hen nights. Similarly, seaside resort towns have become tourist centers of stag and hen parties. These places accommodate visitors that wish to consume adult entertainment usually associated with premarriage celebrations, such as strip clubs, lap dancing, sex toy shops (and the public display of sex toys), cross-dressing, and so on (Hubbard, 2008). In much of this work geographers seek to highlight the privileges *and* oppressions at the intersections of genders and sexualities.

Trans identities have added further complexity to the above scholarship of gender and sexualities. Recent studies by geographers have shown how transphobia and sexism are experienced by trans people in homonormative gay and lesbian spaces, and some have suggested alternative places where support and security can be found. This scholarship challenges any notions that gender is stable and, at the same time, illustrates the intersection of gender and sexuality (see, in particularly Petra Doan's (2010) powerful and moving autoethnographic account of the persistent 'tyranny' of gendered spaces). What is clear from this scholarship is the political urgency to continue questioning, challenging, and subverting the binary system of gendered and sexed spaces. Trans geographies is one way to do this (Browne et al., 2010; Doan, 2010).

Sexuality and space scholarship that recognizes race and ethnicity may highlight the ways homonormative spaces can privilege whiteness and as a consequence are deeply racist (Caluya, 2008). Attention too has turned to the prevailing whiteness of queer scholarship. Jasbir Puar (2006) has provided a compelling account on American homonormativities after 9/11. Other researchers have shown how homophobic discourses are put into operation in order to seek ethnic and national purity by, for example, reproducing narratives of Irishness (and attempting to exclude gay, lesbian, bisexual, transgender, and intersex (GLBTI) performances) at the St Patrick's Day parade in New York City (Mulligan, 2008) and in forming a national closet in Latvia (Waitt, 2005).

Class and sexuality is another fruitful intersection that is receiving more attention in sexuality and space scholarship (Richardson et al., 2009). Jon Binnie (2011: 21) takes an opportunity to highlight three themes "(1) the classing of epistemology and methodology within sexuality studies, (2) the relationship between culture and the economy in framing research on class and sexuality, (3) the significance of space, place, and intersectionality." Privilege and oppression can be illuminated when considering the intersections of class positions, gender, and sexed identities. Yvette Taylor (2011) delves deeply into class divisions of lesbian identity and spaces. She shows how classed identities fracture collective lesbian identities both emotionally and materially. Others have highlighted the class privileges that align with homonormative gay men and lesbian spaces and identities (Holmes, 2009). The confluence of poor, working class, and heterosexuality has also been considered in, for example, Nepal (Richardson et al., 2009).

Work on sexuality, space, and age is another intersection of identities that is beginning to gain prominence. There are accounts of the way in which heterosexual patriarchal discourses in, for example, Vietnam work to control young women. Bringing together race, sexuality, age, and education, Mary Thomas (2011) considers the space of a high school campus for 26 Latina, Armenian, Filipina, African-American, and Anglo girls. Her research shows that while the girls use the 'everyone just wants to get along' discourse, they also perform racism and uphold spatial segregation. Young gay, lesbian, and bisexual youth are the focus of Andrew Gorman-Murray's (2008) study into Australian family homes. Here Gorman-Murray moves beyond geographical literature that has predominantly represented heterosexual nuclear family homes as spaces of exclusion, violence, and abuse for young gays, lesbians, and bisexuals. He notes that while these injustices exist, geographers must also pay attention to how queer youth may queer heterosexual homes and "provide a space for the fluorescence of nonheterosexuality within an apparently heteronormative site" (Gorman-Murray, 2008: 31).

There are important connections between disabilities and sexualities. Geographers have studied the way in which nonnormative sexualities have been categorized as illness, or disease and some studies highlight the challenges that disabled bodies pose to hetero and homonormativities. Work also exists that explores health issues for gay men. (There is enormous scope to examine the interconnectedness between place, (dis) abilities, impairment, and sexual identities although geographers have yet to make a substantial or sustained contribution to this scholarship.) The association of physical ableism with hegemonic notions of beauty and sexuality needs critical examination, as well as research that critiques spatially embodied normativities.

Conclusion

In the first edition of this encyclopedia, Heidi Nast (2001: Health Education and Health Promotion) writes "sexuality-geography research needs to be more theoretically and empirically attuned to differences produced through normative and oppositional constructions of race, gender, class, disability age, religious beliefs, and nation." Her words hold true today. While much contemporary sexuality and space scholarship is attuned to intersections and axis of difference, there is still room for more research to examine these connections.

Over the past decade a substantial corpus of research on sexuality and space has emerged. This research is crucial in understanding the production and expression of sexual identities and sexual practices, whether they be gay, lesbian, bisexual, trans, intersex, queer, asexual, polyamorous, or heterosexual. Despite the rapid growth in work on sexuality and space over the past decade, there is still a great deal of homophobia and heterosexism within the academy. The topic of sex and sexuality cannot just be added to an unchanged geographical discipline, rather the heternormativity of the academy needs challenging in order to expose its absences and institutionalized homophobia. Of course this homophobia and heterosexism also exists well beyond the academy in everyday spaces. Our debates as researchers of sexuality and space shape our disciplinary homes, as well as every other space we may be in. In order to realize and acknowledge the diversity of sexualities, geographers must continue to talk about sex, bodies, erotics, love, pleasure, power, pain, place, and space. It is vitally important to discuss topics such as 'asexuality, polyamory, homeless people having sex, a small town that became known as the sex change capital of the world, and bestiality' in order to push the boundaries of what geographers perceive to be important and relevant sites of investigation (Johnston and Longhurst, 2010: 161). A continued interrogation of sexuality and space is required in order to further understand the myriad of ways in which power, knowledge, and subjectivities encompass sexed, sexy, sensual, and sexual bodies.

Sexuality and the Internet

Aaron Ben-Ze'ev, University of Haifa, Haifa, Israel

Abstract

Cyberspace offers an alternative romantic (and sexual) environment that provides people with easy access to many tempting options. It is a kind of huge, dynamic, electronic bedroom loaded with imaginative interactions. This novel environment has a significant impact upon offline romantic activities. This impact is expressed in increased opportunities, greater self-disclosure, decreased vulnerability, greater satisfaction, lesser commitment, increase in violations of boundaries, and reduced exclusivity. Cyberspace provides technical tools that facilitate the opportunity to conduct several romantic (and sexual) relationships at the same time. Although cyberlove and cybersex are likely to become more popular, they will not replace offline relationships, but rather complement them.

Cyberspace is a very popular new environment in which people pursue and conduct romantic and sexual activities (Goldberg et al., 2008). While in December 1995, only 0.4% of the world population used the Internet, in 2013, it has risen to about 40% (http://www.internetworldstats.com/emarketing.htm).

In this article, I will first briefly describe the nature of cyberlove and cybersex. Then I will examine how these online activities affect people's romantic and sexual behavior, values and attitudes. I will focus on the following major changes in the romantic (which includes the sexual) realm: Increased opportunities, greater self-disclosure, decreased vulnerability, greater satisfaction, lesser commitment, increase in violations of boundaries, and reduced exclusivity. All these changes make cyberspace a more exciting romantic environment, one which has far-reaching implications on sexual behavior, values and attitudes not merely within this environment, but also in offline circumstances.

Like the ordinary romantic environment, cyberspace is not homogenous and there is no 'one theory fits all' approach; the phenomenon of online relationships requires a more complex analysis (Whitty, 2013).

Cyberlove and Cybersex

Cyberlove and cybersex are common and attractive romantic and sexual activities (Ross, 2005). Cyberlove is a romantic relationship consisting mainly of computer-mediated communication. Despite the fact that the partner is physically remote and may be anonymous, the emotion of love is experienced as fully and as intensely as in an offline relationship.

In a broad sense, cybersex (or in slang, 'cybering'), refers to all types of sexually related activities offered in cyberspace. In this sense, the viewing of sexually explicit materials on the Internet is also a type of cybersex. In a narrower sense, which I will use here, cybersex refers to a social interaction between at least two people who are exchanging real-time digital messages in order to become sexually aroused. People send provocative and erotic messages, with the purpose of bringing each other to orgasm as they masturbate together in real time. These messages are typically sent via a private communication, such as an e-mail, instant message, or a chat room. The messages may be of various types – video, audio, and text-based. Although here I mainly refer to text-based cybersex, many of the claims are valid for other types of online communication.

In text-based cybersex people describe body characteristics to one another, verbalize sexual actions and reactions, and make believe that the virtual happenings are real. Cybersex requires the articulation of sexual desire to an extent that would be most unusual in face-to-face encounters. In cyberspace, that which often remains unspoken must be put into words (Doering, 2000). When people are involved in cybersex, they cannot actually kiss each other, but nevertheless the kiss they may send is emotionally vivid and its emotional impact is often similar to that of an actual kiss.

I argue that the active personal role in cyberspace makes this environment more exciting and seductive than that of daydreams, erotic novels, or X-rated movies; hence the temptation to engage in sexual activities is great. The personal imaginary interaction is very seductive. Since the line separating passive observation from full interaction has already been crossed in cybersex, it becomes easier to blur the line separating imagination from reality (Ben-Ze'ev, 2004; see also De Mul, 2010).

Participants in cyberlove take the reality of cyberspace seriously. Thus, people speak of their cybermates or even their online husbands or online wives. People have even got cyber-married and vowed to remain faithful to each other. Some women have claimed that they do not want to engage in cybersex with the first person who asks them, since they want to save their virtual virginity for the right man. Similarly, some say that they do not want to have a one-night cyberstand, but rather wish to have a more extended and meaningful online sexual affair (Levine, 1998: pp. 135–136). Nevertheless, in light of the dynamic and restless nature of cyberspace, such brief sexual activities are very common. The illusory nature of cyberspace does not diminish the need to resort to the same illusory methods used in offline circumstances, such as faking cyberorgasms.

I argue that the presence of interactive characteristics in the imaginary realm of online relationship is a tremendous revolution in personal relationships, as it enables people

to reap most of the benefits associated with offline relationships without investing significant resources (Ben-Ze'ev, 2004).

The interactive revolution in online romantic and sexual relationships has promoted both greater social interaction and more solitary activities. In comparison with standard fantasies, online relationships involve more social activities with other people. However, in comparison with offline relationships, many romantic activities are performed while someone is all alone sitting in front of a computer. Take, for example, cybersex. Compared with offline masturbation, cybersex (like phone sex) is a much more social interaction, as it is done while communicating with another person. While in offline masturbation, orgasm comes courtesy of the person's own hands and mind, in cybersex orgasm also comes courtesy of another person's mind. Cybersex narrows the gap between masturbation and offline sex, as it involves the active contribution of another person. However, compared with offline sexual relationships, cybersex is less social and it can in fact reduce the need for actual social interactions. Moreover, the virtual nature of cyberspace often fails to satisfy real needs. As a married woman wrote to her online lover, "I want a lover who actually touches me."

I turn now to discuss some of the major changes in the romantic and sexual realms that are due to the introduction of the Internet: increased opportunities, greater self-disclosure, decreased vulnerability, greater satisfaction, lesser commitment, increase in violations of boundaries, and reduced exclusivity.

Increasing Opportunities

Cyberspace is an alternative, available romantic and sexual environment that provides people with easy access to many available and desired options.

It is easy and inexpensive to contact desired and willing partners and to perform desired actions. It is easier to find attractive romantic and sexual partners in cyberspace than in bars, shopping malls, or supermarkets; moreover, it is easier to identify available and willing people.

Cyberspace is also highly available in the sense that it is immediately accessible for most people. The great accessibility and convenience of cyberspace make people feel comfortable about entering this space and staying there. One does not have to invest much in order to step into this imaginative, romantic and sexual paradise. Millions of people are eagerly waiting for everyone on the Internet every moment of the day. They are available and it is easy to find them. It must be remembered, however, that, as in offline life, most of those people will not be suitable. The great availability of online romantic and sexual partners enables frequent novel changes, and this makes cyberspace a more dynamic, volatile, and exciting romantic and sexual place. A kind of huge electronic bedroom, as someone remarked.

The many romantic and sexual opportunities in the current cyberspace society make this the best and worst of times for lovers. It is indeed both a happy and a difficult time for lovers – happy in that available, willing potential lovers are all around; difficult in that maintaining a loving committed relationship is harder than before as alternative romantic options are easier to explore and to realize.

Greater Self-Disclosure and Lesser Vulnerability

Two seemingly contrasting features of online relationships are: greater anonymity and greater self-disclosure. Anonymity is associated with concealment, which is contradictory to self-disclosure. However, since greater anonymity reduces vulnerability, it typically facilitates greater self-disclosure, which in turn increases familiarity and intimacy.

Research indicates that there is faster and more profound self-disclosure in online communication than in face-to-face meetings (Joinson, 2003; Tidwell and Walther, 2002). In online relationships people can be partially or fully anonymous: people can conceal their true identity or important aspects of it. Anonymity in online relationships facilitates self-disclosure as it reduces the risks involved in disclosing intimate information about oneself. People can express themselves more freely since they are more anonymous, less accountable, and hence less vulnerable. In the anonymity (or semianonymity) of cyberspace, it is much easier to disclose one's true feelings. Accordingly, it is more likely that in cyberspace the process of self-disclosure will be linear, moving in a unidirectional and cumulative fashion from nondisclosure to near full disclosure. In offline circumstances, the opposing urges to reveal and to conceal makes people oscillate between guarded self-concealment and candid self-disclosure.

Online self-disclosure resembles the 'strangers on a train' phenomenon, where people sometimes share intimate information with their anonymous seatmate (McKenna et al., 2002). Since anonymity in cyberspace is greater than on a train, revealing intimate personal details is more common in cyberspace. Online relationships enable people to hide behind a form of communication that is somewhat 'removed from life.' It is easier to open up to a faceless stranger that you do not have to look at while revealing your secret or to see the next morning. In online relations are similar in this regard: people can freely express their emotions and become emotionally close without being vulnerable. Accordingly, it is also easier to fall in love on the Net.

Despite the reduced vulnerability in cyberspace, the online agent can be hurt as well. In this regard, two major aspects are significant: (1) most of the many high hopes that cyberspace generates are not fulfilled – thereby causing frequent and profound disappointments; and (2) profound self-disclosure leaves the agent's mind naked, without any masks to protect her – and this is a highly vulnerable position for anyone.

Online relationships typically have fewer practical implications than have offline relationships; hence, participants in these relationships are less vulnerable. Indeed, in offline relationships, people tend not to reveal much intimate information until they feel safe. In cyberspace, people are ready to disclose more intimate information since they assume that anonymity and spatial distance reduce the risk of harmful consequences. Sex in cyberspace is safe not only in the physical sense, since viruses cannot travel in that space, but also in the psychological sense that is provided by being anonymous.

Since feeling safe is a major precondition for sexual arousal, the safety provided by cyberspace may explain the vast interest in cybersex (Bader, 2002: pp. 263–276).

Greater Satisfaction and Lesser Commitment

Imagination, which plays a major role in cyberspace, makes this space very seductive since it can free people from the limits imposed by their bodies and contexts (Dreyfus, 2001). Imagination has hardly any practical constraints, and it enables one to depict oneself and the other in a most positive and seductive light – much better than in reality. Online imagination can also complete, in an exciting manner, details upon which our online companions might remain vague. Imagination can therefore entertain our wildest fantasies. The imaginary nature of cyberspace makes it easier to idealize the other; and idealization is an essential element in romantic love and sex (Allbright, 2007; Ben-Ze'ev, 2004).

Emotional imagination can be compared to receiving a salary without earning it. Emotional imagination enables us to acquire various affective benefits, such as feeling better, without carrying out the relevant tasks required for obtaining such benefits (Ben-Ze'ev, 2000). For example, in sexual fantasies one may simulate the pleasure of intercourse with an attractive person without having to build an actual relationship and carrying the burden associated with this. It is obvious that there is no free lunch and we have to pay a price for this unearned emotional salary. The cost will be high if people repeatedly use tactics such as gaining emotional benefits from imaginary relationships; people may, for example, increase the risk of distorting reality to the extent that coping with it becomes not easier, but harder.

Cyberspace is a highly imaginative and active space. Romantic imagination also plays a significant part in offline circumstances, but in cyberspace its role is considerably greater; 'virtual reality' can actually augment fantasy. The many attractive online alternatives in cyberspace, coupled with the imaginative freedom that cyberspace offers, might make a current offline relationship less valued and offline partners less attractive.

Increasing Boundaries Violations

Drawing boundaries is essential for human communities: living with other people necessitates limiting our desires. However, globalization, in which cyberspace is a central arena of action, is essentially an act of crossing, cracking and breaking boundaries. Openness, which is an important aspect of globalization, implies boundary deregulation. Thus, since the activities in cyberspace cut across territorial borders, the feasibility and legitimacy of laws based on geographic boundaries are undermined (Almog, 2002).

Drawing romantic boundaries is particularly difficult since many people perceive love as uncompromising ('There are no mountains high enough, to keep me from getting to you'), and unconditional ('Love will always prevail'). People in love occasionally feel chained by normative boundaries preventing them from acting in accordance with their wilder passions. When in love, people want to 'fly on the wings of love,' where the earthly boundaries do not exist. Cyberspace allows people to crack and violate many normative boundaries with considerably reduced risk (Ben-Ze'ev and Goussinsky, 2008).

To decrease the boundaries violation, people may want to make their normative boundaries more flexible, yet this in turn may weaken the safeguards against further violation. Take, for example, cybersex, where romantic and sexual boundaries are much more flexible than in offline circumstances. This flexibility has not reduced the number of offline violations of boundaries but rather increased it. With the expanded use of the Internet, romantic and sexual cheating has increased. Moreover, even if the sexual cheating is limited to online, partners can lose trust in their loved ones and identify themselves as victims of trauma (Schneider et al., 2012).

The flexible nature of boundaries in cyberspace is not necessarily immoral. On the contrary, living by adhering strictly to strict boundaries may be immoral, as it does not take into account the unique, specific, personal and circumstantial aspects of the lover. In this regard, Stephen Toulmin (1981) argues that "A morality based entirely on general rules and principles is tyrannical and disproportionate … only those who make equitable allowances for subtle individual differences have a proper feeling for the deeper demands of ethics."

Reducing Exclusivity

Romantic, and especially sexual, exclusivity has been regarded as the hallmark of romantic relationships. The current social trend leans toward reducing exclusivity in relationships, and this trend is being reinforced by behavior in cyberspace, where romantic boundaries are very flexible. Reducing romantic exclusivity conflicts with partiality, which is one of the basic emotional characteristics and which enables the agent to focus his resources on one or very few objects. This reduction also goes against the heart of ideal love, i.e., the perception that the beloved is the one and only person suitable for the lover's profound love. On the other hand, such a reduction in exclusivity enhances a different characteristic, that of the need for change and novelty, which generates emotions.

The technology associated with online relationships makes it easier, more convenient, and safer to reduce exclusivity. Modern technology continues to improve the methods available for distant relationships. It does not merely provide more options of meeting willing people, but it also offers a more comfortable way to pursue several romantic relationships at the same time.

The practice of whetting your appetite online while eating at home is a significant element in the process of violating marriage's monopoly on sex for married people. As cybersex is seen as a lesser sin – since it can be considered merely a process of talking that involves no actual physical encounter – some offline partners will tolerate or even support it. Letting your partner know about, and even watch, your sexual activity with another person is significant in the sense that the committed couple knowingly accepts that sexual exclusivity is not a one-degree category that should never be violated. Sexual

exclusivity is thus seen as a continuum, and, in some circumstances, certain points along that continuum may be violated.

As it is difficult to entirely avoid the huge amount of available tempting alternatives that cyberspace provides, the attitude toward romantic affairs is likely to change. As online infidelity and adultery radically increase, it may cause a qualitative change in the agreed meanings of 'infidelity' and 'adultery.' The criteria for inclusion within these categories will become more limited. Thus, harsh descriptions such as 'betrayal' are beginning to fade and softer words, such as 'a parallel relationship,' are becoming more popular. Nevertheless, it is highly unlikely that the chaotic and dynamic nature of cyberspace will completely replace the more stable nature of actual space, as people cannot thrive in complete chaos.

Cyberspace enables participants to conduct several online affairs while still maintaining the primary offline relationship. People may have an online relationship that is different in nature from their offline relationship, and hence the two may not be in conflict – at least not significantly enough to force the termination of one of them. If the offline relationship is more pragmatic, with only a dash of romance, the online affair may be full of romance and with little or no practical implications. One relationship may be mainly sexual, while in the other the sexual aspect may be marginal. Since the two types of relationship fulfill different needs, their coexistence may be beneficial.

In order to reduce the risk of ruining their primary offline relationship, some married people may accept their partner having an online sexual affair, but not an online romantic affair. Others may further limit the sexual affair to a one-night cyberstand. All such limitations are intended to minimize the harm done to the primary relationship. It seems, however, that a more substantial change in our emotional makeup is required for coping with these sexual opportunities while still maintaining some stability in the primary relationship.

The Internet presents a serious threat to monogamous relationships in general, and marriage in particular, since it facilitates not merely pleasurable sexual activities but deep romantic relationships as well. A one-night cyberstand is more available and easier to keep secret, and people are not oblivious to this advantage. On the other hand, the conditions for nourishing a deep loving relationship have also been improved. The Internet provides a most enjoyable and efficient means by which various people get to know each other intimately without the distractions of external factors, such as appearance, age, geographical distance, race, nationality, religion, or marital status. This will increase the number of international, intercultural, and interreligious marriages, ultimately modifying global social norms – in the main, making them more flexible (Barak and Fisher, 2002).

The Internet is not unique in providing opportunities for meaningful romances and superficial sexual affairs; its main novelty is that it offers an environment in which – given a wise and moderate use of cyberspace – both types of relationship can coexist. Indeed, some findings suggest that Internet users who engage in online chats are usually people who are satisfied with their offline social relations and for them, socializing in online chat rooms does not substitute for offline emotional or social needs; rather, it complements their offline relations (Maheu and Subotnik, 2001; Peris et al., 2002).

The Internet encourages other types of changes in romantic relationships. Thus, the prominence of verbal communication in online affairs is likely to increase the value placed on intellectual abilities in romantic interactions. Accordingly, online romances are likely to depend more on the combination of emotions and intelligence, including verbal and intellectual features such as wit, a sense of humor, and good articulation. The value of personal characteristics – as compared to the value of external appearance – will probably increase. The change may have rather, less impact once most computers are equipped with a Webcam, but it will be evident even then as long as distant online relationships continue to be based upon written text.

The Alternative Romantic Environment

Cyberspace provides an alternative environment to the actual one. People do not live exclusively in one environment; rather, they move from one environment to the other. Cyberspace enables participants to explore exciting romantic alternatives without necessarily violating significant personal commitments. Cyberspace provides an outlet for developing alternative emotional ties, without completely ruining the primary offline relationship. When people confuse cyberspace with the actual world, the issue of commitment becomes problematic and emotional and moral difficulties emerge.

The great seductiveness of cyberspace and the effortlessness of becoming involved in online affairs also entail risks: People are easily carried away and the risk of addiction is high. Moreover, the gratification from cybersex is often higher than from offline sexual contacts and it is generated not merely in cases of unsatisfying offline sexual activities (Laier et al., 2013). Like other types of addiction, cyberspace does not merely satisfy needs, but creates new needs that often cannot be met. This may lead to a lower probability of being satisfied with one's romantic lot.

The Internet encourages various types of other changes in romantic relationships. Thus, the prominence of verbal communication in online affairs increases the value placed on intellectual abilities in romantic interactions. Indeed, the weight of conversation – which is essentially an intellectual activity – is far greater in online relationships than in offline relationships. Accordingly, online romances are likely to depend more on a combination of emotions and intelligence, including verbal and intellectual features such as wit, a sense of humor, and good articulation. The value of personal characteristics, as opposed to the value of external appearances, will probably increase. This change may have rather less impact once more conversations are conducted with a Webcam. Still, it is likely that written communication will remain central for many years.

It is highly unlikely that, in the future, either offline or online romantic relationships will cease to play an important role in people's lives. The increased lure of the Net lowers the likelihood that those with access to the Net will restrict themselves solely to offline relationships. However, since online relationships lack some basic romantic activities, such as touching and actual sex, satisfying offline relationships will continue to be considered to be an upgraded and more

fulfilling relationship. Learning to integrate cyberspace and cybersex with actual-space in the romantic domain will be a major task for our society (Wysocki, 2012). Indeed, initial indications suggest that more than one-third of marriages in America now begin online. In addition, marriages that began online, when compared with those that began through traditional offline venues, were slightly less likely to result in a marital break-up (separation or divorce) and were associated with slightly higher marital satisfaction among those respondents who remained married. This suggests that the Internet may be altering the dynamics and outcomes of marriage itself (Cacioppo et al., 2013).

Today, dreams are no longer the major tool for imagining a better situation. Cyberspace has become more efficient for such a purpose. Cyberspace allows two lovers to feel as if they are directly connected – as if their bodies do not interfere, allowing their hearts to be in direct communication; they feel as if their souls are melting. People often describe their online relationship as 'dreaming while awake'. People delight in these dreams. However, a life of mere dreams and sleep are dangerous because they are not connected to reality. Online romantic relationships are valuable when they complement, rather than replace offline relationships. The value of dreams, as well as that of Cyberspace, is that they are interspersed with reality.

Social networks, such as Facebook, have become a central place for initiating and maintaining new romantic (including sexual) relationships. The new technological means of communication have shaped romantic relationships. People are all potentially in connection with each other, which provide further depth to their online relationships. The possibility of having so many friends further undermines the value and feasibility of romantic exclusivity.

Online relationships usually have the characteristic of 'unfinished business' since as long as they are not transformed into offline relationships, there is something missing from them. In this sense, they are similar to an extended period of courtship, and accordingly emotional intensity remains high even for a long period. A paradoxical aspect in this regard is that although online relationships are romantically and sexually intense because of, among other factors, their incompleteness, such incompleteness involves the wish to transform the relationship into a more complete one – something that usually decreases the intensity and may lead to the termination of the relationship.

Future changes will inevitably modify present social forms such as marriage and cohabitation, and current romantic practices relating to courtship, casual sex, committed romantic relationships, and romantic exclusivity. In light of what we have learned from recent history, we can expect the further relaxation of social and moral norms; this process should not be considered a threat, as it is not online changes that endanger romantic relationships, but our inability to adapt. Catherin Hakim (2012) argues that "If the pill made pre-marital sex among young people a lot easier, the internet facilitates playfairs among older married people."

Cyberspace has a significant role in maintaining intimate relationships between partners who live apart and meet only intermittently. This is also true of those marriages in which couples are compelled to live apart for some time, usually because they have jobs in different places. Commuter marriage is a rapidly growing form of distant relationship. Such relationships also exist among dating couples and in extramarital affairs; in these groups, cybersex, conducted through either regular or video chats, is very popular and enables the partners to maintain a certain level of intimacy.

Online affairs may make it easier to deal with the problem of regret, as it offers lower-risk affairs. Such affairs provide the excitement associated with romantic and sexual affairs, hence avoiding romantic dissatisfaction in the short term and regret in the long term. The lower degree of risk and moral criticism associated with such affairs also enables participants to avoid short-term regret and actual harm. Avoiding romantically exciting affairs may succeed in preventing short-term regret about the harmful consequences of our actions. As time goes by, however, regret over inaction is stronger, and avoiding pleasant actions becomes more and more difficult.

In a way, cyberspace forces people to face reality – a reality that often includes one's actual, disappointing romantic relationship. One cannot avoid unpleasant reality by leading oneself to believe that better alternatives are not available. Cyberspace takes an intermediate position between reality and sheer fantasy. The escape into cyberspace is not essentially an escape into fantasy; it is often an escape into a semireality that presents our everyday life in a more realistic manner. Sometimes, offline relationships can benefit from such an arrangement. Indeed, people testify that their online affair has been a beneficial, learning experience and has helped them to recognize many positive aspects of their offline relationship.

One way to prevent long-term regret is to encourage people to act on their impulses more often; people should focus less on the short-term consequences of their action and more often 'just do it.' However, this advice could be dangerous as the status quo is usually safer than trying something new. Awarding greater significance to unwise actions might promote risky behavior and decrease chances of survival. Cyberspace provides a way to cope with this dilemma: it lets people act on their impulses, hence reducing long-term regret, and it significantly reduces the risks involved in such behavior, thus reducing the chance of short-term regret.

What Is Next?

An endless search in cyberspace for a better alternative brings frustration and misery rather than happiness. Settling for one's lot, which is an important way to achieve profound happiness, is even more imperative in the cyberspace era. However, if you compromise and accept something much less than your dream demands, it can ruin your happiness as well. We need to find the optimal balance between trying to achieve our dreams and being able to be satisfied with our lot. Current society requires people to make more compromises, since we are aware of more promising alternatives (as compared with our own current situation); however, it is more difficult to make those compromises, since the alternatives are easier to achieve.

Future lovers may have to make more compromises and their frustration in not achieving the imaginary perfect partner might increase. But those lovers have also a greater chance of being satisfied with their romantic relationships in a way that

will not cause them to feel that they are making significant compromises.

Cyberspace poses specific difficulties in finding a romantic framework that will suit all lovers. Nevertheless, love itself is flourishing as a result, among other things, of the use of the Internet. It is more possible now than ever before to find the one you have been waiting for all your life; it is more difficult now to stay with this person for ever.

The test that future society will face is whether it can complement ordinary romantic activities, just as the telephone complements ordinary social activities, or whether they will merely replace these activities with less valuable ones, as television has frequently done.

Sexuality: Cultural Aspects

Daniel Jordan Smith, Brown University, Providence, RI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article examines cultural aspects of sexuality and reviews the contributions of social science research to this field of knowledge. Two features are emphasized: (1) the social construction of sexuality, which produces immense cross-cultural diversity and (2) the extent to which societal preoccupations with sexuality are often about much more than sex itself, providing fertile data for social analysis. The article is organized into six substantive sections representing significant domains of scholarship in this area. These sections focus on premarital sex, marriage, extramarital sex, gender and sexuality, non-heterosexuality, and the global AIDS epidemic.

Introduction

Sexuality is both an intimate and very public domain of human social life, essential to biological and social reproduction. Two dimensions of the relationship between culture and sexuality are fundamental. First, despite its basis in human biology, sexuality is culturally constructed in powerful ways. Sexual identities and orientations, the meanings of sexual behavior, and the social consequences of these behaviors vary tremendously across cultural contexts. Second, in every society, the cultural meanings of sexuality are about much more than sex. In order to understand the reasons why people adopt various sexual identities and why they engage in sexual behavior in the ways that they do, it is necessary to situate sexuality in a broader social context. Societal norms and practices around sexuality, along with popular interpretations and political responses to them, are often implicit means by which people debate, contest, or simply give expression to many other issues besides sexuality. Studying the cultural aspects of sexuality is not just a way to understand sexuality better, but it can also be a revealing window onto culture and society more generally.

The social sciences have contributed immensely to the realization that sexuality is culturally constructed. This notion builds on the broader conception of the social construction of reality, but knowledge about the cultural underpinnings of sexuality draws, in particular, on insights from feministic scholarship, from comparative and cross-cultural studies of human sexuality – particularly in anthropology (Rosaldo et al., 1974; Davis and Whitten, 1987) – and more recently, from queer studies. In criticizing patriarchal social structures, exposing a male-privileged division of labor in society, and challenging accepted 'knowledge' about men and women in both popular culture and science, feminist scholars pointed to the centrality of control over women's bodies and their sexuality as a vehicle for reproducing gender inequality (Ortner and Whitehead, 1981). Essential to the feminist critique was the understanding that both gender and sexuality were in large measure human-made, socially constructed categories. The implication is that sexuality is not simply biological destiny, but a domain of political and social action, where shared cultural meanings have significant effects.

If feminist critiques of gender inequality provided one foundation for a broad understanding of the cultural construction of sexuality, anthropological studies of sexuality across a vast array of societies provided another enormous body of evidence showing that sexuality is highly variable across cultural contexts. The wide diversity of identities, beliefs, and practices around sexuality catalogued and analyzed by anthropologists and other cross-cultural researchers has demonstrated conclusively that sexuality is a deeply social domain of human life. The challenge in the social sciences is no longer to prove sexuality's culturally constructed aspects, but to investigate what these are, explain what accounts for differences across societies, and evaluate the consequences – across a huge range of contexts.

Whether in history or in the contemporary world, human communities commonly focus on – in many cases, one might even argue, obsess – over things related to sexuality in ways that are not adequately explained by the stakes associated with sexuality itself. As indicated above, feminist scholars have demonstrated incisively how societal preoccupations with women's bodies and sexuality often serve to express, enact, and enforce a much broader politics of gender (Fausto-Sterling, 2000). But societal obsessions about sexuality are not only about women. For example, in many places, public controversies over homosexuality or non-heterosexuality focus more on male sexuality than female sexuality, and these concerns have been interpreted by social scientists as enacting and enforcing societal norms about masculinity (Connell, 1987; Gutmann, 1996). But popular and political concerns about sexuality are often about much more than gender. Societal preoccupations with sexuality – whether they take the form of local rumors, frenetic media coverage, or legislative debates over proposed laws related to sexuality – are often a means by which much wider concerns about social life are expressed. People – indeed communities and whole nations – frequently conduct much bigger social and political debates in the idiom of discourses about sexuality. For example, heated debates about gay marriage in the U.S., about rape in India, and about homosexuality in Uganda, to name just three recent cases, while important issues in their own right, are also vehicles by which these societies express and contest even larger issues.

The cultural landscape of human sexuality is, of course, vast. This article briefly summarizes some of the cultural aspects of sexuality in relation to six topics: premarital sex, marriage, extramarital sex, gender, non-heterosexuality (or the commonly used western acronym of LGBTQ sexuality – lesbian, gay, bisexual, transgender, and queer), and the AIDS

epidemic. In each section the themes of the cultural construction of sexuality and the wider meanings of discourses about sexuality are employed to organize and limit what is said about otherwise huge topics in and of themselves. The section on the AIDS epidemic concludes the article both because it is arguably the newest major arena of sexuality research and because it exemplifies so clearly how societal preoccupations with sexuality involve stakes and have consequences much wider than sexuality itself.

Premarital Sex

Across most societies, if not all, marriage (see below) is the socially prescribed sphere in which sexual relations are expected and approved of, above all, because of its function as the means for biological and social reproduction. And yet at the same time, the institution of marriage and the social rules that accompany it have also created the very possibility of what is widely known as 'premarital sex.' Cultural preoccupations with premarital sex in the contemporary world are driven, at least in part, by a modern demographic reality: across nearly all societies people are marrying at later ages, creating a much longer window of opportunity for premarital sex (Westoff, 2003). Until relatively recently in human history the gap between puberty and marriage was short. The value placed on formal schooling and higher education for both men and women around the world, and other accompanying social changes, have expanded the premarital period and stimulated cultural responses that are complex and often contradictory. In many societies, premarital sexual activity is seen by young people as a marker of modern identity and simultaneously condemned (especially by older generations) as an emblem of problematic social change, connoting failures of collective morality, and gender and generational stability under siege (Smith, 2000).

On the one hand, studies in many different cultural contexts have shown that young people feel being sexually active before marriage is part of becoming an adult; but much more than that, premarital sex is a way that young people represent themselves as educated, modern, urban, and in tune with contemporary fashions. Even in contexts where premarital sex comes with both health risks – such as unwanted pregnancy or HIV infection (see more below) – and social risks – such as sanctions imposed by parents, kin, and even some peers – evidence suggests that the cultural appeal of premarital sex looms large in young people's sexual decision-making and behavior. While social contexts vary dramatically, the combination of later age at marriage and the widespread (arguably global) association of premarital sex with modern youth identities has meant that young people around the world are increasingly engaged in premarital sex and navigating its positive and negative cultural consequences.

While young people in many societies seem drawn to the social rewards that are conferred by being sexually active before marriage, they also sometimes face significant cultural backlash, mainly because premarital sexuality (especially female premarital sexuality) is often seen as a harbinger, symbol, or consequence of a much wider array of social changes about which people are often anxious, including rural-to-urban migration, increases in female wage labor, growing levels of educational attainment, and the proliferation of global media (Utomo and McDonald, 2009). Collective cultural responses to changes that threaten generational hierarchies, challenge established gendered divisions of labor, or create other new inequalities are often voiced, in part, through discontents about young people's behavior, particularly their sexual behavior. While social anxiety about sexual behavior is arguably a timeless human preoccupation, given sexuality's elemental role in social reproduction, widespread contemporary concerns about premarital sex reflect specific concerns about social reproduction in a world of urbanization, growing inequalities associated with the expanding reach of capitalism, a changing gendered division of labor, and a long duration between puberty and marriage.

Research on the cultural aspects of premarital sex is often closely tied to the (real or imagined) implications of young people's sexual behavior for their health, whether because of unwanted pregnancy, sexually transmitted infection, or HIV and AIDS (see more below). The literature on premarital sexual behavior documents a wide variety of practices associated with specific cultural contexts (Widmer et al., 1998). Some of this scholarship shows very particular health consequences related to specific cultural practices (e.g., initiation rites that include circumcision). But across many different settings, it is the common tension between cultural values that encourage young people to engage in premarital sex and social mores that prohibit or punish it that influence many of the scenarios that lead to negative health outcomes.

Marriage

As noted already, in nearly every cultural context marriage is the most positively sanctioned domain in which sexual relations are expected to occur. Although sex in marriage is universally expected across cultures, the rules are culturally specific. Given that human societies are deeply invested in the cultural rules about sexuality because sex is elemental to both biological and social reproduction, sexuality in marriage is especially important because it is the institution through which reproduction is most intensely regulated. Classic anthropological theories about the function of marriage in human social organization, whether they emphasize alliance or descent, point to its central role in social reproduction. Throughout much of human history, in many societies, sexuality, marriage, and reproduction were (and to an extent remain) inextricably connected.

Even in contexts where procreation is seen as the primary purpose of sex in marriage, cultural norms and understandings of proper sexual conduct vary tremendously (Thornton and Fricke, 1987). In polygynous societies, for example, a man's sexual access to multiple wives is commonly tightly prescribed. In many contexts, the importance of pleasure and its expression in marital sex, including women's pleasure, is highly valued, while elsewhere it is considered inappropriate to emphasize or overtly express physical enjoyment. In some settings all sex, including marital sex, is considered potentially polluting and dangerous (Wardlow, 2006).

The perceived relationship between sex and marriage has changed considerably in recent decades. The idea that love and romance should be a basis for marriage has spread globally,

one factor in precipitating a decrease in arranged marriages (Hirsch, 2003; Coontz, 2006). Although cultural differences are still powerful – and push these new forms of marriage in locally inflected directions – in general, the rise of what has been called 'modern marriage,' 'choice marriage,' 'love marriage,' 'companionate marriage,' or 'romantic marriage' has meant that sexual intimacy, communication, and mutual pleasure in marriage have become more explicitly valued. These global trends seem to elevate the importance of sex itself – apart from its reproductive function – in contemporary marriages worldwide. This pattern coincides with, and indeed may be partly explained by, demographic transition, in which parents are having few children. The relationship between spouses has become more central in the entire endeavor of family making. That being said, rising rates of divorce may also accompany the increasing emphasis on romantic intimacy as a basis for marriage, for when feelings of love subside or transform with time, the basis of the marriage may seem to be weakened as well.

Finally, it is worth noting that societal debates about marriage – which seem to animate religious discourse, popular political discussions, and so-called 'culture wars' in many societies – can be constructively interpreted as conversations and contests over the relationship between sexuality and social reproduction. Whether it is the concern over rates of divorce, gay marriage, teenage pregnancy, forced marriage, or 'sugar daddies' (wealthy, often married men having sex with economically dependent single young women), when societies are collectively preoccupied about issues related to sex and marriage, they are typically voicing concerns about much wider issues of social reproduction – about the kind of values, practices, people, and institutions they will have in the future.

Extramarital Sex

If the fact and social importance of marriage create and shape the possibility and cultural meanings of premarital sex, the same is true of extramarital sex. Perhaps the most widespread characteristic of extramarital sex across cultures is that it is simultaneously proscribed and commonly occurring. Many explanations for the prevalence of extramarital sex – especially men's extramarital sex, which is believed in most societies to be more prevalent – either explicitly or implicitly assume a biological basis. Humans – or at least men – are often presumed to be wired in ways that make monogamy and fidelity difficult. Interestingly, these naturalizing narratives prevail in many societies, even when they are not connected directly to science (or explanations meant to pass for science).

But culturally attuned research on extramarital sexuality has shown that such behavior can be explained in social terms: it is socially organized and in various ways culturally rewarded; it has social functions and meanings that cannot accurately be reduced to natural instincts or drives; and patterns of extramarital sex change over time and vary significantly across contexts. For example, recent comparative research on men's extramarital sexuality has found the social factors like migration for employment (often separating husbands and wives for long periods over significant distances), the growing importance of conspicuous consumption as a marker of class, as also men's participation in same-sex peer group activities, all serve to increase the likelihood of men's extramarital sexual relationships (Hirsch et al., 2009). In short, men's infidelity is not simply biological destiny, but a culturally constructed arena of human activity.

Less research has studied women's extramarital sexual behavior. Arguably this is because women's extramarital sexuality is more stigmatized, and therefore more hidden (and perhaps also less common), and not necessarily because women are biologically different, or at least certainly not solely because they are biologically different. Rates of extramarital sex by gender have not been empirically verified across most cultures. Indeed, the difficulty of such research attests precisely to the culturally charged quality of sexuality. To the extent that research has explored women's extramarital sexual behavior, a diversity of cultural values and patterns of behavior across societies is apparent (Wood and Eagly, 2002).

Like premarital sex, extramarital sex can become the object of social scrutiny, a problem that people in many different societies will point to as emblematic of (or sometimes even a causal factor in) a wider range of social problems. The fact that in many cultures women's participation in premarital and extramarital sex draws more collective ire than men's is a result of the persistence of gender inequality and the role of cultural mores about sexuality in creating and maintaining gender double standards more generally.

Gender and Sexuality

Now largely taken for granted, one of the fundamental contributions of feminist scholarship was to demonstrate that sex and gender are not the same thing (Fausto-Sterling, 2000; Rubin, 2004). Rather than biological sex-determining gendered identities and roles, gender was revealed to be a highly variable, culturally constructed domain, deeply influenced by and consequential for social life. But even as feminist scholarship and a rich body of literature in gender studies more broadly have examined gender as a socially constructed category, sexuality remains deeply connected to gender and connects biological sex and gender in powerful ways. Although biological sex does not mechanistically determine gender, sex and sexuality are nonetheless important components of the social construction of gender.

As such, though gender and sexuality are distinct concepts and different dimensions of human social life, they are often inextricably intertwined. If it can be said that most, if not all, human societies are preoccupied – often even obsessed – with sexuality as an arena of social discourse and moral regulation, it can also be usefully hypothesized that a good deal of the fixation on sexuality is about defining, defending, contesting, and reproducing a gendered division of labor that is fundamental to social organization, and to the production and reproduction of various forms of hierarchy and inequality (Connell, 1987). Social and moral concerns about sexuality are a foundation for cultural constructions of gender differences and the social and political consequences that follow.

One of the predominant findings in studies of the cultural aspects of sexuality as it relates to gender is that patriarchal social organization in many ways depends upon shaping and

controlling women's participation in public and political arenas through regulation of their sexuality (Kandiyoti, 1988; Inhorn, 1996). Patterns of gender inequality maintained through the regulation of women's sexuality can be overt and explicit, such as through laws or religious edicts, or – and perhaps more commonly – they can be informal, tacit, and so taken for granted that they often go unnoticed as forms of social control. When popular concerns about women's sexual morality and behavior become objects of popular discourse and vehicles for the expression of social discontent, as happens so frequently across the globe, they are often proxies for wider social and political concerns. Women's sexual bodies and behavior come to stand for larger tensions and contests regarding social reproduction. Many forms of social inequality are connected to, and arguably depend upon, maintaining aspects of gender inequality.

While feminist critiques and a focus on women's oppression comprise major strands of social science research on the cultural aspects of sexuality as they relate to gender, over the last couple of decades a growing body of work has focused on the social construction of masculinity (Connell, 1995; Gutmann, 1997). Ideas and practices around manhood are equally implicated in wider social and political issues. Much of this work suggests that masculinity is more fragile than it is stereotypically conceived of. Further, men's sexual bodies and behavior are objects and arenas wherein not only masculinity itself is made and expressed, but also – as with women's sexuality – domains where much of the work of social reproduction is conducted. To the extent that social life – including fundamental features of social inequality – depend on ideas about gender and a gendered division of labor in society, and to the extent that the cultural construction of gender mobilizes ideas about sexuality for its power, men's sexuality is as implicated as women's sexuality, although as the dominant and often unmarked category it is less studied.

Non-Heterosexuality

Culturally oriented research on what is referred to in many western societies as LGBTQ (lesbian, gay, bisexual, transgender, and queer) sexuality has demonstrated that it is instructive to analyze social ideas and practices related to non-heterosexual orientations as being situated in a culturally constructed domain in which ideas and practices vary tremendously across social contexts. Although the preferred terms vary for speaking about sex that is not between 'straight' partners, this article uses the concept of 'non-heterosexuality' to encompass the range of orientations that are glossed in Europe and North America as LGBTQ. Like other socially marked sexual identities and behaviors, part of the reason non-heterosexuality receives so much popular attention across societies is because public discourse about it frequently stands for larger anxieties around gender politics, the role of families in reproduction, forms of economic privilege associated with marriage, and much more (Weston, 1993). Scholarship on the cultural aspects of non-heterosexuality has demonstrated not only huge cross-cultural variation, but also a common pattern in which highly charged public debates and widespread homophobia signal much wider worries about society.

One of the signature contributions of cross-cultural social science research on non-heterosexuality has been to show that Western ideas and assumptions about homosexuality and LGBTQ identities are not necessarily shared in other contexts, and patterns of behavior vary significantly (Reddy, 2006). For example, in many societies, the notion of a gay identity is not common (although globalization has certainly made gay identities available to some people in the non-Western world). While in many Western contexts non-hetereosexual practices are associated with both a defined sexual orientation, and even an identity, in many settings people participate in same-sex behaviors while still maintaining what might be called hetero-normative identities and behavior, such as marrying and having children with members of the opposite sex.

In Western societies, advocates for homosexual rights frequently point to evidence for the biological basis for homosexuality. It is well beyond the scope of this article to say much about this, but it is worth noting that Western understandings of biology as a fundamental basis for explaining behavior certainly contribute to an environment in which claiming that homosexuality is biologically based would appear to be a strong argument for combating stigma associated with it. Such an observation says nothing about actual genetic or biological realities; it simply points out that the relative importance of biology as a basis for recognizing and conferring legitimacy is itself culturally variable (Fausto-Sterling, 2000). While some cross-cultural variation in non-heterosexual practices (and beliefs about homo-, bi-, and transsexuality) might well be partly a response to the stigma associated with them in many settings, the extent of the variation certainly suggests that – like heterosexuality – non-heterosexuality is a profoundly socially constructed arena of human behavior.

The stigma surrounding non-heterosexuality that is common in so many societies stems, at least in part, from the ways that public discourse about it is linked to concerns about social reproduction. When societies engage in animated – and often ugly – debates about whether to punish homosexuality with imprisonment, or even death (as has been occurring in various African countries in recent years), or when national debates about gay marriage create polarizing divisions, such as in the United States, what is at stake is not simply attitudes toward homosexuality, but people's concerns about social reproduction more generally. In this regard, non-heterosexuality is a fertile topic through which societies debate, contest, reproduce, and change what they collectively want for the future. Concerns about social reproduction – about the kinds of values, norms, people, and institutions that will constitute society – are voiced and contested in culture wars over those seen as aberrant. Homophobia is not just about sex, it is about society. While people may be mistaken in associating or blaming homosexuality and other stigmatized forms of sexual behavior for a range of societal ills, these connections nonetheless make such prejudices harder to undo.

Sex, Culture, and AIDS

Some scholars have argued that nothing in history has generated more research and scholarship about the cultural aspects of sexuality than the global AIDS pandemic (Parker, 2001). The

AIDS research industry devoted to understanding the cultural aspects of transmission has, of course, produced a plethora of knowledge about culture and sexuality. This research has contributed to understandings about the variety of cross-cultural beliefs and practices related to sexuality, confirming the basic social science insight that sexuality is a highly contextual, fundamentally socially constructed arena of human activity. Further, recent scholarship has demonstrated that the stigma associated with AIDS, challenges faced (and sometimes caused) by public health prevention and treatment apparatuses, and the factors associated with HIV risk are all fundamentally bound up in social processes that are about much more than sexually-transmitted infection routes (Setel, 1999; Smith, 2014).

It is impossible to summarize the thousands of articles and books about AIDS, sexuality, and culture here, but what stands out from this huge literature is the absolute necessity of situating people's sexual decision-making and behavior in a specific cultural context. Every form of sexual activity occurs in situations where economic and social circumstances are significant and cultural (and often religious) meanings matter. The most insightful literature on sexuality in the era of AIDS has shown that it is important not to allow assumptions about sexuality – whether they are popular local ideas or prevailing scholarly orthodoxy – to go unexamined. Over and over again, research has shown that reality is different than what is assumed.

A few examples from studies of sexuality in the context of AIDS are important reminders that good social science research on the cultural aspects of sexuality is vital in order to understand properly why people behave the ways they do, in addition to generating insights into how it might be possible to design and implement effective public health interventions that affect such behavior. For example, so-called transactional sex, where sex is exchanged (typically by women) for some sort of material support (typically from men), is often seen as a potential driver of HIV risk and infection, and as stemming from women's economic destitution. But research has shown that transactional sex frequently involves aspirations over and above mere survival; relationships commonly entail deeper social and affective connections; material support can signal emotion as much as economics; and women often exhibit much more agency than is stereotypically assumed (Hunter, 2010). Addressing the risk of HIV infection in such relationships requires confronting these complex dynamics.

Perhaps nothing illustrates more clearly how culturally mediated understandings of sexuality influence behavior than does the response of many people (particularly in Africa, although in a variety of other societies) to the promotion of condoms as a form of protection from HIV infection. Because AIDS is a stigmatized disease, and because in many societies the epidemic has come to be understood as symbolic of a kind of collective social and moral crisis, individual infection is often interpreted as a sign of personal ethical failure, and even as sin. In this context, ironically, condoms have become symbols of the disease and their use can be seen as signaling that users are the kind of people (or are having the kind of sex) that could spread HIV (Preston-Whyte, 1999). As a result, condom use is sometimes eschewed not because people don't want to prevent HIV infection, but because the cultural meanings of condoms make their use problematic (Smith, 2014).

A final point drawn from reviewing much of the literature on culture and sexuality as they relate to the AIDS pandemic provides an important cautionary lesson with regard to research not only on AIDS, but also on the cultural aspects of sexuality more generally. In distinguishing good and bad scholarship about culture and sexuality, it is important to be aware of the difference between research that offers culturally contextualized explanations and work that might be described as 'culturalist.' Culturalist accounts tend to attribute sexuality and sexual behavior to some sort of timeless notion of culture that often invokes tradition and fails to situate the cultural aspects of sexuality in their social, political, and economic contexts. The idea of 'African sexuality' as it has been invoked to explain the continent's AIDS epidemic is one of the most egregious examples of culturalist fallacy: both scholarly research and media representations of the epidemic have often blamed so-called traditional African sexual practices for the high rates of infection there. While it is necessary to avoid such fallacies, situating sexuality and sexual behavior in cultural context is essential not only to combat the AIDS epidemic, but also to facilitate understanding the human condition more generally.

Conclusion

Two fundamental aspects of the relationship between sexuality and culture organized this article: (1) the fact that sexuality is a culturally constructed domain of human behavior and (2) the reality that cultural preoccupations with sexuality are often about much more than sex. These two aspects are connected. Ultimately, each reflects the extent to which the cultural dimensions of sexuality are related to the centrality of sexuality in social reproduction. Sexuality is such a culturally significant domain because it is fundamental to the way that societies create and reproduce not only people, but also the values, institutions, and life-ways that are the very fabric of social life.

Abstract

This article provides an overview of the different forms of formal sexuality education. It includes definitions of key terminologies used in this field, a review of the standards and frameworks developed to guide sexuality education programs, and a brief critical review of the evidence of effectiveness for different approaches to sexuality education. It also discusses the current public policy landscape for sexuality education.

Introduction

Sexuality education is a lifelong intentional process by which people learn about themselves and others as sexual, gendered beings from biological, psychological, and sociocultural perspectives (Goldfarb and Constantine, 2011). Sexuality education exists in some form in every country and culture. Formal sexuality education is often implemented through school curricula, and may also be offered by health care, faith-based, or community-based organizations. Much of sexuality education, however, is informal, occurring within the process of sexual socialization. Through this process individuals acquire attitudes, values, ideas, and patterns of behavior related to sexuality by observing and interacting with family members, peers, and other members of their community, and by consuming electronic and print entertainment, advertising, news, and public information that have explicit or implicit sexual content.

Most formal sexuality education programs around the world focus on adolescents, serving individuals ranging in age from the preteen years into the early twenties. Sexuality education can be an important tool in helping adolescents navigate the biological, cognitive, and social transitions that transform how they look, think, feel, and interact with others. However, most formal sexuality education does not have such a wide-ranging agenda. In many countries and communities, the concept of sexuality education is highly polarizing and political. In these contexts, the policies that undergird and fund sexuality education programs often reflect the interests and concerns of organized pressure groups. This can result in programs that are restricted in content as well as their purposes, which may include fostering a preference for sex within marriage, discouraging premarital sex, teen pregnancy or teen childbearing, lowering youths' risks of becoming infected with HIV or another sexually transmitted infection, or helping youth avoid sexually coercive behavior.

Terminology and Definitions

Across countries, the terminology used to describe sexuality education policies and programs conveys information regarding the lens through which sexuality education is viewed. In Eastern Europe, for example, family life education is a common terminology. Similarly, Nigeria uses a National Family Life and HIV Education Curriculum (UNESCO, 2010). In some countries, apprehension about HIV/AIDS has resulted in sexuality education programs being subsumed within national HIV prevention programs. For example, with concerns rising about HIV/AIDS in the 1990s, Portugal changed the name of its national program from Program for Personal Development to Program for Health Education, thus embedding their sexuality education program into a more explicitly health oriented framework (Parker et al., 2009). In the United States, the most common forms of sexuality education are generally referred to as abstinence-only (or sometimes abstinence-only-until-marriage) and abstinence-plus. In addition, youth development programs with a pregnancy postponement or sexual risk reduction goal are also sometimes viewed as sexuality education programs. For example, the positively evaluated Carrera Pregnancy Prevention Program has been described as "age-appropriate sex education with access to medical, mental health, academic support, financial literacy, and career planning services" (Carrera, 2013).

In general, these different terms and corresponding approaches can be categorized into two broader categories that reflect historic tensions between competing visions in the field – 'sex education' and the more limited 'comprehensive sexuality education' (Goldfarb, 2009). Sex education has generally referred to instructional approaches focused on preventing pregnancy and disease primarily through controlling young people's behaviors. The course content of sex education typically encompasses anatomy, sexual behavior, reproductive functioning, and methods of disease and pregnancy prevention.

Comprehensive sexuality education, on the other hand, is based on the view that individuals' physical and mental health can be enhanced by a holistic and scientifically grounded understanding of sexuality. Preventing pregnancy and disease represent only one component of a broader goal of fostering sexual health. Comprehensive sexuality education approaches also include a substantial focus on topics such as gender issues, relationships, sexual development, sexual orientation, and pleasure. In this article, the more generic term 'sexuality education' is used to encompass both the sex education and comprehensive sexuality education approaches, as well as other forms of education that address sexual health and sexuality.

Abstinence-Only and Abstinence-Plus Sex Education

Approaches classified as sex education can be further categorized into two divergent categories: abstinence-only and abstinence-plus sex education. Abstinence-only sex education has as its exclusive purpose, teaching the social, psychological, and health gains of abstaining from sexual activity, including, among other things, the idea that a mutually faithful, monogamous relationship within the context of marriage is the expected standard of human sexual activity (Trenholm et al., 2008). Programs under this umbrella explicitly exclude content related to contraception or condoms – other than to note failure rates – as well as safer sex, abortion, and many other topics. These programs tend to focus on religiously based concepts such as chastity, virginity, purity, and the sanctity of marriage.

Abstinence-plus sex education (also known as abstinence-based sex education) promotes the avoidance of risky sexual behaviors, stressing abstinence as the best way to reduce rates of unintended pregnancies and sexually transmitted diseases (STDs). Using a disease prevention, or harm reduction approach, such programs are distinguished from abstinence-only programs by their public health underpinnings and specifically their inclusion of information and instruction about contraception and other protection. These programs are often incorrectly referred to as comprehensive because of the addition of these topics, leading to confusion with the term comprehensive sexuality education. True comprehensive sexuality education embraces a much wider range of goals and topics than just those directly related to disease and pregnancy prevention.

Comprehensive Sexuality Education

Viewing sexuality as a multifaceted force in human life, comprehensive sexuality education programs go beyond disease and pregnancy to address human development, gender issues, sexual orientation and identity, love, sexual health problems, sexual attraction, pleasure, parenting, and sexual and reproductive rights. In addition, these programs are often designed to develop skills in critical thinking, media literacy, and communication. One example of a guiding paradigm for comprehensive sexuality education is the Circles of Sexuality model, developed by Dailey (1981) and adapted by Goldfarb and Constantine (2011). This model identifies five overlapping components of human experience – sensuality, intimacy, sexual identity, sexual health and reproduction, and sexualization – that combine to create the totality of human sexuality.

Controversy attaches to whether comprehensive programs foster or teach sexual morality. Religiously inflected concepts such as chastity and virtue are not typically presented. However, abstinence can be encouraged as a developmentally appropriate and self-protective choice for youth. In addition with the inclusion of discussions (and sometimes skills development) about couple communication and gender relations, comprehensive programs tend to focus more than abstinence-only or abstinence-plus programs on the mindsets and skills that protect against sexual coercion and foster sexual autonomy.

Comprehensive sexuality education has been widely adopted in schools in the Netherlands and Sweden, as well as in other countries of Western Europe and some developing countries (Berne and Huberman, 1999; International Sexuality and HIV Curriculum Working Group, 2009; Parker et al., 2009). In the United States, public schools generally do not follow a comprehensive sexuality education model but private schools and community institutions may, as illustrated by the six-level lifespan sexuality education program, Our Whole Lives, published by the Unitarian Universalist Association and the United Church of Christ.

Addressing Diverse Groups of Learners

Because young people are developmentally and otherwise diverse within even a narrow age range, a 'one size fits all' strategy is rarely appropriate in sexuality education. If learners feel that the norms of their group or culture are not being addressed in a sexuality education program, they will be less likely to internalize its messages. Complicating matters, many people identify with more than one cultural group. They may, for example, relate simultaneously to cultural values and customs of their ethnic group, the strictures of their religion, and the imperatives of their sexual orientation, all of which may conflict.

Some groups of youth are chronically underserved by sexuality education programs. Among the groups least well-served are sexual minority youth – including those who identify as lesbian, gay, bisexual, transgender, or questioning (LGBTQ) – and learners with disabilities.

LGBTQ Youth

Most sexuality education programs, unless specifically designed for LGBTQ youth, employ a heteronormative framework for almost every discussion about contraception, safer sex, relationship building, resistance skills, and sexual violence or abuse, among other topics. Scenarios used for role-play, critical thinking, or values-clarification activities inevitably involve a male and female. Sometimes, well-intentioned programs will use gender-neutral names such as Corey and Jesse, but the content and issues raised are consistently based on a heterosexual paradigm. Furthermore, most sexuality education programs address the topics of sexual orientation, gender identity, and homophobia minimally, if at all. This is especially true of the abstinence-only programs. As a result, LGBTQ youth often find themselves alienated, marginalized, and invisible.

People with Disabilities

Two common and mutually contradictory myths about people with disabilities are that they are not sexual at all and that they are unable to control their sexuality. Research has shown that these and other misconceptions foster discomfort among families and educators about offering sexuality education to people with disabilities. Because children with disabilities are at a greater risk for sexual exploitation and abuse, the first inclination among parents and caregivers often is to keep them ignorant in an effort to protect them. Not educating young

people with disabilities, however, increases rather than decreases their risk. People with disabilities have the same range and intensity in their sexual needs and their desires for love and intimacy as their nondisabled peers. Recognizing disabled students in sexuality education communicates this important message to all.

Public Policies and Legal Frameworks

A variety of public policies converge to create the legal framework for sexuality education and to shape its provision in any given location (see **Box 1** for examples of relevant policy areas). These policies establish a foundation that helps determine the relative ease or difficulty with which sexuality education can be implemented, who receives it, and in what form it is available (Constantine, 2008; Parker et al., 2009).

The public policy context for sexuality education extends from the international level to the local level. At the international level, declarations ratified by United Nations member countries establish global support for sexuality education from diverse perspectives including economic development, gender equity, and health (see **Box 2**). Similarly, regional conventions have been developed to create a shared vision of sexuality education. One such declaration was signed in Mexico City in 2008 by health and education ministers from Latin America. The Latin American Ministerial Declaration mandates school-based sexuality and HIV education throughout the region (UNAIDS, 2008). These declarations provide an important impetus for the establishment of national programs in many countries. However, sexuality education is a long way from being institutionalized in every country, and the amount and nature of local programming typically reflects a country's income levels as well as its political culture and health needs (UNESCO, 2012).

There is a great variety in sexuality education policies across, and often within, countries, states, and school districts. National agencies responsible for sexuality education policies include ministries of education and of health and departments focused on HIV/AIDS, family planning, youth, sports, and others. In Europe, the Ministry of Education is most commonly involved in cooperation with one or more departments.

Some countries, such as Nigeria, have created a national curriculum and have taken on responsibility for its implementation at the central level (UNESCO, 2010). In the United States, however, while sexuality education funding is provided by federal agencies, responsibilities to specify and implement program approaches are conveyed to states and then to individual school districts.

School-based delivery of sexuality education is common across the globe, but countries' policies and programs also differ substantially in the specification of curriculum content, location of implementation, designation of the educator, required educator training, age(s) at which sexuality education should be provided, and in whether parental permission is required. A few countries employ an integrated approach to sexuality education, one in which content is spread across several subject areas. In the United States, however, most students receive sexuality education as a part of biology or health classes (Hoff et al., 2000).

Many countries rely on staff or volunteers from nongovernmental organizations, or a combination of school and community organizations to implement sexuality education programs. Some programs designate peer education as their mode of delivery for sexuality education (e.g., India, Indonesia, Bangladesh; UNESCO Bangkok, 2012).

Policies generally specify the time frame during which sexuality education should be delivered to students through designating either the age or the grade (i.e., schooling level) at which students should receive it. Experts generally agree that an early and developmentally appropriate start to sexuality

Box 1 Policy areas relevant to sexuality education

Policy areas specific to school-based sexuality education:

- Governmental agency responsibility
- Mandatory provision of sexuality education
- Content areas
- Age at which provided
- Parental notification (opt-in and opt-out)
- Person responsible for teaching
- Training required for teacher
- Confidentiality

Related policy areas:

- Age of consent for sexual and reproductive health care services
- Abortion
- Contraceptive provision including condom availability
- Age of mandatory schooling
- Nondiscrimination
- HIV/AIDS testing and treatment
- Testing and treatment for STDs
- Needle exchange

Box 2 International conventions related to sexuality education

1994 International Conference on Population and Development (ICPD) Programme of Action
1999 Overall review and appraisal of the implementation of the Programme of Action of the International Conference on Population and Development (ICPD + 5)
1995 United Nations Fourth World Conference on Women Platform for Action
2000 United Nations Committee on Economic, Social, and Cultural Rights
2001 General Assembly Special Session on HIV/AIDS, Declaration of Commitment on HIV/AIDS
2003 United Nations Committee on the Rights of the Child
2006 United Nations Convention on the Rights of Persons with Disabilities

education is important. In Europe, of the 25 countries for which data are available, 14 countries require that sexuality education begin at 10 years of age or younger, 7 countries require that it begin between 11 and 12 years of age, and 4 countries require that it begin after 12 years. In practice, a majority of these countries implement sexuality education starting around 12 years of age (Parker et al., 2009). In a 28-country, Asia–Pacific study, fewer than half of the countries implemented sexuality education at the primary school level (UNESCO Bangkok, 2012).

The choice between opt-in, opt-out, or no parent permission required in sexuality education is often set by national or local policy, rather than by individual schools. Opt-in policies are those that require parents or guardians to actively provide permission for their children to participate in sexuality education, whereas opt-out policies require notification of parents, but put the onus on the parents to actively request that their children be excluded from participation. Although many countries do have policies that allow parents to exclude their children from sexuality education, others (e.g., Germany) have mandated sexuality education as a part of the national curriculum and, therefore, do not provide parents the option to exclude their children from the sexuality education curriculum.

Additional policies that address the wider context in which sexuality education is implemented, including policies such as confidentiality, availability to youth of reproductive health services, testing and treatment availability, among others, are also important aspects of the policy landscape for sexuality education.

A Case Study: United States

The United States offers an example of a decentralized system that has several layers of sexuality education policies ranging from the national level to the local level. Mandates for sexuality education exist in 23 of the 50 states and in the District of Columbia, whereas 34 states require the provision of HIV education. Twenty-six states require that sexuality education stress abstinence, 11 states require that abstinence be covered, 18 states require that sexuality education include information on contraception, and 19 states require that HIV education include information on condoms (Guttmacher Institute, 2013).

This diversity across state policies reflects national controversy surrounding sexuality education. The heated debates triggered by the topic illustrate its sensitive and often politicized nature, and a lack of consensus about what content should be included and who should teach it (Constantine, 2008; Constantine et al., 2007; Irvine, 2002; Luker, 2007; Parker et al., 2009). These debates have contributed to, as well as resulted from frequent policy shifts nationally and within states. For example, currently in 2013, federal funds for sexuality education in the United States flow to states under two different laws that reflect distinct and mutually inconsistent priorities. The Title V abstinence-only-until-marriage education law (the Abstinence Education Provision of the 1996 Welfare Law, P.L. 104–193, 1998) has for nearly 20 years funded states' abstinence-only sexuality education programs. In contrast, since 2012, states may apply for federal funds through the Personal Responsibility Education Program (PREP) – part of the Patient Protection and Affordable Care Act (P.L. 111–148) – for abstinence-plus sexuality education with a focus on pregnancy outcomes. Thus, states may choose to apply for federal abstinence-plus (PREP) funds, abstinence-only (Title V) funds, or both, even though the implementation guidelines for the two program approaches are incompatible.

State policies generally specify the amount and type of sexuality education that schools provide, determine course content, and set the terms of parental authority over children's participation. Like national policies, some states' policies have lurched from one philosophical approach to another. For example, in 2012, Wisconsin shifted from a more comprehensive approach to sexuality education to a more restrictive policy that reestablished an abstinence-only-until-marriage approach for the state's secondary school students (SIECUS, 2010). On the other hand, in 2005, Oregon made a shift from a risk-focused approach toward a youth development model that embraces sexuality as a natural part of adolescence (Nystrom et al., 2013).

Educational approaches typically vary across school districts within parameters set by state law, as illustrated by the California Comprehensive Sexual Health and HIV/AIDS Prevention Education Act of 2003 (Education Code ss. 51930–51939). This law mandates a minimum of 2 hours of HIV prevention education across grades 7 through 12 and further requires that all sexuality education taught in public school districts or otherwise supported by state funds be age-appropriate, bias-free, medically accurate, and include discussion of all contraception methods approved by the US Food and Drug Administration. Furthermore, materials must be appropriate for students of all genders, sexual orientations, ethnic and cultural backgrounds, and accessible for English language learners and students with disabilities. An evaluation of the implementation of the 2003 California law, however, found that many school districts do not fully comply with these mandates. Students continue to receive incomplete, and in some cases inaccurate, information about sexuality through their school-based sex education programs (Combellick and Brindis, 2011).

Frameworks and Standards

In multiple separate attempts to create a common vision, bring cohesion to the field, and to provide guidance for those seeking to develop and implement sexuality education, various organizations have developed frameworks or standards to help sexuality education. These frameworks correspond to either abstinence-only, abstinence-plus, or comprehensive sexuality education and make apparent the philosophical as well as practical differences that separate these three broad approaches.

An Abstinence-Only Sex Education Framework

Unlike the two more expansive approaches that are discussed below, abstinence-only sex education in the United States is shaped by a legislatively mandated framework that is explicitly prescriptive. The Title V abstinence-only-until-marriage

education law (discussed above) defines abstinence education as an educational or motivational program with the following eight characteristics:

- Has as its exclusive purpose, the teaching of social, psychological, and health gains to be realized by abstaining from sexual activity.
- Teaches abstinence from sexual activity outside marriage as the expected standard for all school-age children.
- Teaches that abstinence from sexual activity is the only certain way to avoid out-of-wedlock pregnancy, STDs, and other associated health problems.
- Teaches that a mutually faithful and monogamous relationship in context of marriage is the expected standard of human sexual activity.
- Teaches that sexual activity outside of the context of marriage is likely to have harmful psychological and physical effects.
- Teaches that bearing children out-of-wedlock is likely to have harmful consequences for the child, the child's parents, and society.
- Teaches young people how to reject sexual advances, and how alcohol and drug use increases vulnerability to sexual advances.
- Teaches the importance of attaining self-sufficiency before engaging in sexual activity.

These features have been used as criteria for states to receive Title V funds for their programs. Exactly how closely a funded program must align with these eight points has been vigorously debated over the years, and federal program guidance on compliance has changed with successive presidential administrations.

An Abstinence-Plus Sex Education Framework

Abstinence-plus education has a longer history than abstinence-only, and a larger body of evaluative studies is employed to support effectiveness claims for curricula-based abstinence-plus programs. The National Campaign to Prevent Teen and Unplanned Pregnancy (Kirby, 2007) has published a set of 17 desirable characteristics for sexuality education programs, which include three pertaining to curriculum content:

- Focus on clear health goals – the prevention of STDs/HIV, pregnancy, or both.
- Focus narrowly on specific types of behavior leading to these health goals (e.g., abstaining from sex, using condoms or other contraceptives), give clear messages about these types of behavior, and address situations that might interfere with them and how to avoid those situations.
- Address sexual psychosocial risk and protective factors that affect and change sexual behavior (e.g., knowledge, perceived risks, values, attitudes, perceived norms, and self-efficacy) and change them.

International Comprehensive Sexuality Education Frameworks

The comprehensive sexuality education frameworks discussed next reflect the missions of the three organizations that developed them. The World Health Organization (WHO) framework (WHO, 2010) aims at reconceptualizing sexual health as a core element of overall health rather than as merely a component of reproductive health. Centered around standards and principles of international human rights agreements, this framework calls for complementary action across multiple domains, including education, to support population sexual health. The United Nations Population Fund framework (UNFPA, 2010), developed from a convened 2010 meeting of global leaders in sexuality education, likewise intends to advance human rights, gender equality, and sexual and reproductive health. Finally, the International Planned Parenthood Federation (IPPF, 2010) framework also employs a rights-based approach.

World Health Organization framework. This framework asserts that sexual health recognizes "the desire of individuals and couples of all sexual orientations and any background to have fulfilling and pleasurable sexual relationships, and its concerns go beyond fertility and reproduction to encompass issues such as sexual dysfunction and disability, and violence related to sexuality" (WHO, 2010: p. iv). According to this framework, comprehensive approaches to sexuality education are likely to focus on:

- prevention of sexually transmitted infections and HIV, contraception, and the mechanics of fertility and reproduction;
- the role of pleasure, eroticism, and satisfaction;
- gender differences, inequalities and human rights, and about the negative and positive effects of gender norms;
- the importance of responsibility and joint decision-making, and training in communication and negotiation skills; and
- sexual and gender identity and sexual choice.

United Nations Population Fund (UNFPA) report. This report (UNFPA, 2010) affirms that comprehensive sexuality education is a human right, arguing that all young people should have access to effective sexuality education programs that are comprehensive, rights-based, and gender sensitive. According to this report, measures of program effectiveness should track changes in gender equality and human rights, as research shows these to be correlated with better sexual and reproductive health. The UNFPA report offers the following recommendations for comprehensive sexuality education:

- Address norms around gender and sexuality, and promote equality, empowerment, nondiscrimination, and respect for diversity.
- Develop indicators that go beyond the biomedical to measure effectiveness, including nonhealth indicators, and evidence of other valuable outcomes of sexuality education.
- In school systems, integrate sexuality, gender, and citizenship objectives into educational goals, and incorporate them across the curriculum.

International Planned Parenthood Federation (IPPF) *framework*. This framework identifies seven essential components of comprehensive sexuality education: gender, sexual, and reproductive health and HIV, sexual rights and sexual citizenship, pleasure, violence, diversity, and relationships. The framework uniquely identifies pleasure as one of the essential components of sexuality, asserting "the right of all young people to enjoy sex and express their sexuality in the way that

they choose" (IPPF, 2010: p. 5). Not offering detailed messages or objectives, the IPPF framework has been purposefully designed for broader application than just in schools. IPPF acknowledges that sexuality education happens formally and informally, in a variety of settings including youth clubs, hair salons, waiting rooms, and often by peer educators. Thus, IPPF created this framework to be a force for collaboration among different youth-serving agencies and nongovernmental organizations.

United States Comprehensive Sexuality Education Frameworks

National Guidelines Task Force framework. Led by the Sexuality Information and Education Council of the United States (National Guidelines Task Force, SIECUS, 2004), a task force of educators, health professionals, and representatives from national US organizations proposed guidelines for comprehensive and developmentally appropriate school-based sexuality education for kindergarten through 12th grade. The guidelines are organized into six key concepts: human development, relationships, personal skills, sexual behavior, sexual health and society, and culture. The guiding vision for this framework is a portrait of a 'sexually healthy adult,' which includes a list of behaviors corresponding to sexual health relating to each of the key concepts. The guidelines identify the primary goal of sexuality education as the promotion of sexual health, and specify four areas to be addressed in pursuit of this goal: providing accurate information related to sexual matters; exploring students' attitudes, values, and insights; cultivating skills in interpersonal relationships; and fostering responsibility (National Guidelines Task Force, SIECUS, 2004).

Future of Sexuality Education national standards. A set of minimal and essential standards has been developed by a team of experts from the fields of health education, sexuality education, public health, public policy, and sexual health advocacy through the leadership of Future of Sexuality Education (FoSE) consortium of leading US sexuality education organizations. The intent of these standards is to foster wider and more consistent provision of sexuality education across the United States, and to help educators make optimal use of the limited time that is allocated to sexuality education in US schools (which averages 3.1 h across all elementary grades, 6 h in middle school, and 8.1 h in high school, according to the FoSE report). The standards include seven topic areas: anatomy and physiology, puberty and adolescent development, identity, pregnancy and reproduction, STDs and HIV, healthy relationships, and personal safety (Future of Sex Education Initiative, 2012).

Evidence of Effectiveness

An extensive body of research exists on the effectiveness of sexuality education interventions in reducing adolescent risky sexual behavior. Hundreds of individual studies have been conducted, along with numerous syntheses, including narrative reviews, programs-that-work lists, and meta-analyses (statistical cumulations of results across multiple evaluations). A large proportion of this research is from the United States.

In any study of program effectiveness, the choice of primary outcomes is critical. Behavior-change outcomes, such as reducing sexual activity and increasing condom and contraception use, have been largely prioritized in program evaluations in this field. Notably missing from this research are outcomes of positive sexuality and behavior, for example, the ability to enter into and maintain healthy relationships, strong communication skills, experiencing positive romantic and sexual relationships, and asserting one's sexual rights and respecting the rights of others. This is consistent with the predominance of research focused on abstinence-plus and abstinence-only curricula and programs, as opposed to fully comprehensive sexuality education.

The largest and most rigorous sexuality education evaluation to date was a United States congressionally mandated 5-year randomized trial of abstinence-only education programs (Trenholm et al., 2008). This study of four popular abstinence-only programs showed no significant differences between program participants and control students on the primary outcomes of number of sexual partners, expectations to abstain, and reported rates of pregnancy, births, and STDs. These results were reinforced by a large-scale observational study employing the Centers for Disease Control and Prevention's National Survey of Family Growth, which also indicated no differences in teen pregnancy rates among adolescents who reported having received abstinence-only sex education, versus those who reported receiving no sex education (Kohler et al., 2008). This study also provided evidence of positive outcomes to those who reported having received abstinence-plus curricula – half the risk of teen pregnancy compared to those who reported abstinence-only sex education and 40% of the risk compared to those who reported no sex education, as well as moderately decreased likelihood of engaging in vaginal sex compared with those who received no sex education.

Studies to test the effectiveness of specific individual abstinence-plus sex education programs have yielded less compelling evidence. Although numerous evaluations have reported positive effects of abstinence-plus programs, most of these evaluations have taken place at the local school district, or community level, and they suffer from some of the common methodological flaws and biases typically associated with these types of evaluations (see Constantine, 2013, for a critical review). Some narrative reviews have led to conclusions of effectiveness for the best of these programs, and some reviews have resulted in lists of recommended evidence-based programs and strategies. But rigorous research syntheses have yielded more cautious conclusions. For example, the authors of the two most prominent meta-analyses conducted in this area, sanctioned by the Campbell Collaboration and the Cochrane Collaboration, concluded that the evidence of effectiveness for abstinence-plus programs in lowering rates of sexual initiation and pregnancy risk was inconsistent, and these authors also commented on the dearth of high-quality evidence on program effectiveness in this area (Scher et al., 2006; Oringanje et al., 2009).

These mixed findings, based on syntheses of multiple evaluations of abstinence-plus programs, seem to contradict the readily available lists of evidence-based programs compiled and publicized by national policy and advocacy

groups, and by the US federal government. In general, the criteria of acceptable evidence of effectiveness necessary for a program to be included on these lists are not stringent. For example, regardless of the number of evaluations conducted and the number of outcomes tested in each evaluation, only one statistically significant outcome is typically required to earn a place on the list. This is referred to as the one study, one outcome fallacy (Constantine, 2013). The problem with this approach is illustrated by a list of 28 programs certified as evidence-based by the US Department of Health and Human Services' for its Teen Pregnancy Prevention Program funding eligibility. According to the Coalition for Evidence-Based Policy (2010), an independent research-use watchdog group, only 2 of the 28 listed programs had strong evidence of effectiveness in prevention of pregnancy or STDs.

In spite of weaknesses in the research base and its policy uses, several broad conclusions are supported by the full body of research evidence on sexuality education effectiveness. First, abstinence-only approaches as typically conceived and implemented have shown limited potential. Second, abstinence-plus approaches that directly focus on promoting behavioral change and include instruction on condoms and contraception methods have better potential, and evidence is accumulating of some modest positive effects overall. Third, with few exceptions, the effectiveness of specific individual abstinence-plus programs and curricula is not well supported by the available evidence. This does not necessarily mean that these programs are ineffective, just that the nature and quality of the available research is inadequate to answer questions at the individual program level. Fourth, true comprehensive sexuality education approaches have not been well studied. Overall, it is fair to say that the full potential to enhance adolescents' sexual health and development through sexuality education is not being realized by the currently popular abstinence-only and abstinence-plus models.

Sexuality in Australia

Juliet Richters, University of New South Wales, Sydney, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Australia is largely secular, with about 50% reporting a religion in surveys. Attitudes are tolerant, with a majority regarding homosexual acts and abortion as acceptable, and few disapproving of premarital sex. However, sex outside a committed relationship is widely disapproved of. Use of contraception is high. States differ in legislation and policing of the sex industry. Just over half of adolescents have sexual intercourse before they leave high school. Condom use at first intercourse is high, but many adults do not use condoms even with casual partners. Sex education is very patchy. HIV has remained largely concentrated among homosexually active men.

Introduction

The international impression of sexuality in Australia may be one of a free and easy beach culture. The reality is more complex, reflecting an ongoing tension between a tolerant set of secular attitudes and a repressive desire to control sexuality, keeping it within bounds and behind closed doors. The impression of a freely hedonistic culture is drawn on by the designer of the front cover of Frank Bongiorno's recent history of sex in Australia (2012), which shows a naked woman running carefree into the ocean. In reality, naked swimming or sunbaking is illegal in Australia, except at a few designated nude beaches. Even babies and toddlers are expected to wear swimming costumes at beaches and swimming pools, though it is claimed that this is to protect them from paedophiles rather than to protect the public from the sight of their genitals.

The Cultural Climate

Media

Media treatment of sexuality – or at least of research into sexual health – is fairly balanced and calm. Response to the launch of the first large national survey of sexual behavior and attitudes (the Australian Study of Health and Relationships, ASHR; Smith et al., 2003a) in 2003 included a double page spread in the broadsheet *Sydney Morning Herald* and serious coverage in other newspapers and radio programs. Headlines such as 'We're a broadminded lot, most of us' (*Sydney Morning Herald*, 9 April 2003) were common. Journalists now draw on these representative sample data rather than the Kinsey figures, which had become almost folklore, treated as eternal fact despite being very located in the time and place of mid-twentieth-century America. Journalists gave enormous attention to statistics on age at first intercourse, perhaps reflecting the concern among parents about the sex lives of their children, and to frequency of intercourse. Published statistics about sex are a benchmark against which people evaluate their own performance as adequate or inadequate.

Even the later publications from this project that might have prompted more disapproval, such as a journal article on bondage and discipline, 'sadomasochism' or dominance, and submission (Richters et al., 2008), were greeted with respect or amusement (rather than derision or outrage) in the media. The very fact that Australia's first major sex survey was directly government funded is significant. A decade earlier, the first UK study (Johnson et al., 1994) had its funding blocked by the Thatcher government and was eventually run with funding from the private Wellcome Trust. At the same time the first major United States survey (Laumann et al., 1994) had its funding blocked by the first Bush administration after having successfully gone through the usual process of scientific peer review, and was run with a greatly reduced sample size.

Media sex scandals are rare in contemporary Australia; the public mostly regard prominent people's sex lives as their own affair, rather than evidence of thorough-going moral turpitude. A 2013–14 scandal about a trade union official, Craig Thomson, who used his union credit card to pay a brothel, focused not so much on the sexual nature of the services but on his fraud in using union money for personal purchases. Before 27 years, former Prime Minister Malcolm Fraser was caught without his trousers in a Memphis hotel corridor, but this did not bring about his downfall.

Attempts to undo the careers of prominent people using sexual scandal have met with limited success. High Court Judge Michael Kirby, whose career started before the legalization of gay sex, when being 'out' as gay was not an option, was accused in 2002 of using an Australian Government car to cruise rent boys in Sydney. It was a foolish target to accuse of such a lack of probity, and the claim was disproved (Bongiorno, 2012: pp. 288–289). Former Justice Kirby, who is proud to bring his lifetime partner to official events, is now a greatly respected senior gay man. His name has been suggested as a possible next governor (Queen's representative) of New South Wales (NSW).

Attitudes

Antidiscrimination laws introduced by gay liberation activists in the 1970s and 1980s have had long-term effects on attitudes; even though Australians with less education, from non-English-speaking backgrounds, and people with a religion are less likely to be tolerant of homosexuality (Rissel et al., 2003a). The concentration of openly gay people in public service jobs and academe – where antidiscrimination is perhaps taken more seriously than in the private sector – has led to slow changes such as state health department funding for antiviolence projects

to protect gay people and to the normalization of same-sex relationships within the *de facto* category. The conservative government of Prime Minister John Howard altered the *Marriage Act* and the *Family Law Act* in 2004 to explicitly exclude same-sex partnerships from legal marriage. In response, campaigns for legal same-sex marriage have achieved majority public support even though the main practical reasons for campaigning for gay marriage in the US do not apply in Australia, as it is already illegal to discriminate against a person (e.g., by refusing to let a dwelling, or having different rules for insurance entitlements) on the grounds of (homo)sexuality or marital status. Members of same-sex couples are assessed on their joint incomes when applying for means-tested government benefits, just as heterosexuals are, whether legally married or not.

Although surveys in Australia have shown that Australians are more tolerant of abortion and homosexual sex than Britons and Americans (Michael et al., 1995; Scott, 1998; Johnson et al., 1994), they respond equally disapprovingly to questions about people in committed relationships having sex with someone else. For example, in ASHR, 78% of respondents agreed that "Having an affair when in a committed relationship is always wrong" (Rissel et al., 2003a), and in the 2009 Australian Survey of Social Attitudes, 89% agreed that "a married person having sexual relations with someone other than his or her husband or wife" was always or almost always wrong. This is largely matched by behavior. In ASHR, only 5% of men and 3% of women in regular relationships for more than a year had had sex with anyone other than the regular partner in the past year (Rissel et al., 2003b).

Sexual Health and Sexual Illness

Australia has received worldwide recognition for its response to the emergence of HIV/AIDS in the 1980s. Due to a combination of favorable circumstances, and the early actions of a few people who fought for legal and health policy changes such as antidiscrimination law and freely available injecting equipment (Baxter, 1992; Blewett, 2003), Australia does not have a widespread HIV epidemic. The strong response by the gay community led to a drop in partner numbers and support for condom use before government information and prevention programs were in place. Despite recent increases in diagnoses, the prevalence of infection remains around 1 in 1000 (Kirby Institute, 2013). Even among prisoners, HIV rates are low.

Early preventive activity to encourage 100% condom use among sex workers was successful, and STI testing rates remain high. It has been said that chlamydia rates are higher in Canberra schoolgirls than among sex workers in Australia (Professor Basil Donovan, at the Australasian Sexual Health Conference 2010). Some brothels and workers, with the support of funded sex worker health organizations, have attempted to normalize condom use for fellatio as well as for vaginal (or anal) intercourse, but compliance with this is mixed, with some establishments advertising 'bareback blow jobs'.

Chlamydia notification rates have been climbing inexorably since tests such as the polymerase chain reaction test became available in the late 1980s, allowing testing of urine samples. Chlamydia is now the most notified communicable disease, much higher than the next most commonly notified infections, gastroenteritis in an institution and influenza. Although the ongoing rise in chlamydia does not appear to have led to a corresponding increase in hospital admissions for pelvic inflammatory disease, chlamydia notifications act as an indicator of exposure to infection, and are unsurprising given the high rates of unprotected sex, especially among heterosexuals.

Australia's success in responding to HIV/AIDS and addressing STIs, especially among homosexually active men, has come at a cost. A focus on disease means that program success can be measured, but it has also meant that broader sexual health and well-being is neglected. In most states, policies for HIV/STI control remain separately from family planning, sex education, maternal health, and sexual assault. The exception is indigenous sexual health policies, which acknowledge that a 'holistic' or integrated approach is necessary.

Research and prevention programs focus on high-risk groups such as gay men, sex workers, and indigenous people and to a lesser extent adolescents and young people, largely neglecting the sexual concerns of the huge majority of people in Australia. This focus worked well in the early years of the HIV/AIDS response, as the epidemic was focused among gay men. The desire to control the sexuality of young people is apparent, as elsewhere, though somewhat more realistic, with only minor influence of the US abstinence push in the 2000s.

Contraception

In ASHR of women exposed to the risk of pregnancy, 95% used some form of contraception (Richters et al., 2003). Of those who did not, the most common reason was some version of an abdication of deliberate pregnancy planning: 'leave it to chance', 'do not care', 'forget', or 'have never got pregnant'. The next most common reason was experience of side effects or contraindications. No woman said she wanted contraception but could not access it. Prescriptions for low-income patients are subsidized, making hormonal contraceptives relatively accessible. Higher use of sterilization in regional and remote areas points to a possible difficulty with access for temporary methods.

In a country where about 50% of people report no religion in telephone surveys (though 78% nominated one in the 2011 Census, presumably because they regarded it as an official document that should reflect their baptism or confirmation status), religion is not a powerful influence on social policy. In ASHR, no women explicitly cited religious objections as a reason for not using contraception – though discomfort of religious origin might be expressed through general reluctance to plan pregnancies or a lingering fear that contraception is unnatural or unhealthy (Richters et al., 2003).

Although there are still people whose contraceptive practice (or lack of it) dismays doctors, it could be argued that many women in Australia have fewer children than they desire rather than too many (Cannold, 2005; Macken, 2005).

Childbearing

Rising rates of recourse to assisted conception techniques including *in vitro* fertilization are influenced by Australia's

pattern of delayed childbearing, which is common to other developed countries where effective contraceptives are easily available. The median age of first-time mothers increased by 2 years over the 1990s and 2000s. Since 2005, more babies have been born to women of 35–39 years of age (once regarded as 'elderly primiparas') than to women of 20–24 years of age. The effect of this is increasingly to make early childbearing a phenomenon concentrated among working-class or underclass women, certain ethnic communities and indigenous women. The higher maternal and perinatal risks associated with early childbearing, as in most women who bear children early tend to have poor social support, give ammunition to those arguing that early childbearing (whether 'early' means before 16, 18, 20, or even 25 years) should be prevented, whatever the childbearing choices of the young women concerned, who may well value babies above further education, or realistically estimate their chance of employment as very low. In other words, their opportunity costs for childbearing are much lower than for the educated middle class.

Abortion

Legal abortion is available in all states, though it remains on the Crimes Act in some states, legalized only by court precedent when performed by a medical practitioner. Thus moral debates about abortion affect its availability and cost. Abortion is not treated in the same way as other gynecological procedures and may incur out-of-pocket costs to the patient of several 100 dollars.

Abortion statistics are hard to come by, as there is no formalized recording mechanism and many abortions are paid for privately without recourse to claims on Medicare. A rough estimate is that in Australia about half of pregnancies are intended, and about half of unintended pregnancies are terminated. Termination rates – i.e., the proportion of total pregnancies that are deliberately terminated – are higher in young women under 25 and women over 45, presumably because pregnancies are less likely to be welcomed by women still in full-time education or not yet in a long-term relationship, and by women who had completed childbearing many years earlier.

The issue has been avoided by politicians for decades as it is seen as a 'no-win' topic, likely only to alienate some noisy opponents without gaining extra support from other voters. Partly as a result of controversy about abortion, there is a very heavy emphasis in clinical practice on fail-safe contraceptive use even for women in whom pregnancy would be very unlikely.

Sex Education

Some form of sex education is part of the school syllabus in all Australian states, but the reality of provision varies widely. Science courses cover mammalian and human reproduction, but lack practical information such as conception and do not engage with issues such as sexual harassment or homosexuality.

In NSW, for example, the high school Personal Development, Health and Physical Education syllabus includes material on sexual health, including STI prevention and contraception, but this is not taught in all schools. As well as state schools, attended by 65% of the high school (12–18 years of age) population, there are systemic Catholic schools and independent schools, often also run by religious institutions, which sometimes do not teach sex education at all, or present reproductive information solely as something that students may need later in their married lives.

Teenagers complain that they are taught 'plumbing' but that it is 'scientific' and not useful to real life (McKee et al., in press). Thus although excellent material for teaching sexuality education was developed in the 1980s and earlier by family planning associations and other bodies, its emphasis on values clarification and engagement with sexual diversity has not been carried through into the reality of most adolescents' time at school even today.

Young People

National surveys of the sexual behavior and attitudes of secondary school students have been conducted every 5–6 years since 1992. These have reflected quite high levels of knowledge about HIV/AIDS – presumably a result of the mandated teacher training and school programs of the late 1980s and the 1990s – but less knowledge about other STIs (Smith et al., 2009).

Despite such programs, folk concepts of risk are resilient, so that even educated young adults cling to the notion that one cannot acquire an STI from someone who is well-off and clean, or in one's own social circle (Crosbie et al., 2013). This leads to high rates of unprotected intercourse at all ages, in the context of high rates of sex with casual partners and sequential monogamy (one-on-one relationships) without STI testing in between. Even for sex that people themselves define as 'casual', only about 40% of heterosexuals always use condoms. Gay men are more diligent condom users; 87% always use condoms for anal sex with casual partners (de Visser et al., 2003a). In gay community surveys, of those with casual partners, 38% report having had any unprotected anal intercourse in the previous 6 months (de Wit et al., 2013).

The school surveys have also revealed a pattern of experience of sexual practices – or acquisition of sexual skills, to put it another way – over the teen years. A majority (71%) of Year 10 students (aged 15–16) surveyed in 2008 had experienced sexual kissing, but only 27% had had intercourse. Of Year 12 students (aged 17–18), 56% had had intercourse and 58% had had oral sex. Most students reported positive feelings about sex, but 38% of young women reported having had unwanted sex at some point (Smith et al., 2009).

Students who leave school earlier, both those who drop out and those who leave to attend vocational college, tend to initiate sex earlier. University students tend to have first intercourse at a later age, and a significant proportion, especially students from Asian backgrounds (many of whom have attended school overseas) are virgins when they commence university. Many have inaccurate knowledge about HIV risks in their home countries (Song et al., 2005) and may be ill-equipped to operate as sexually active independent adults in an Australian university context, for example, by seeking prescriptions for

contraception (Burchard et al., 2011). Australia has large numbers of overseas tertiary students, mostly from eastern and southeast Asia.

National surveys of adults have revealed that the age at first intercourse has fallen over the past several decades, so that people who were born in the 1940s had a median age at first intercourse of 18 years for men and 19 years for women, but for those born in the 1980s the median age was 16 years (Rissel et al., 2003c). As 16 years is the legal age of consent to intercourse in most states, this means that a large minority of teenagers start having intercourse at an age when it is technically illegal. Although many doctors and family planning clinics would be unlikely to make an issue of this unless they thought the teen patient was at serious risk of abuse (Bartholomew, 2009), teenagers may not be aware of this. A disjunction between socially normal (i.e., common, even if not publicly accepted) behavior and the law remains.

In recent decades, young people have been more likely to have oral sex, and some initiate it before they have had intercourse, seeing oral sex as sexual play or 'not real sex'. This is replacing an older view of noncoital practices (except perhaps for manual sex or 'petting' as foreplay) as more risqué and more forbidden than intercourse itself, despite the risks of pregnancy and much higher risks of disease transmission associated with coitus. Anal intercourse is a less common practice, though again the cohort born after 1950 is more likely to have tried it. One reason for the increase may be that the response to HIV/AIDS in the 1980s brought both condoms and anal intercourse into public discourse. Smutty talk about 'frenchies' or Wetchex (a brand name) of condoms and hushed mentions of 'unnatural practices' in divorce cases reported in afternoon papers were replaced by open arguments and information about HIV prevention policy in broadsheet newspapers and on television.

Even parents and teachers approaching sexual issues from a feminist perspective seem to fear oral sex as a possible locus for male exploitation in demanding unreciprocated or unrewarding fellatio from girls, rather than seeing it as a form of sexual play in which girls may experiment sexuality while avoiding both the physical risks of intercourse and its social importance in defining relationship status – or conversely defining girls as sluts if they have intercourse outside a girlfriend–boyfriend context. The double standard is receding; for example, young women report more similar sexual practices and partnering to young men (Grunseit et al., 2005; de Visser et al., 2003b). But qualitative studies repeatedly encounter stories of 'slut-shaming' that constrain young women's sexual agency while rewarding young men for 'scoring' (Albury, 2002). Fear of being thought a slut can make it difficult for young women to openly buy or carry condoms, access adult advice, attend doctors or negotiate fairly with males.

Teenagers from 15 years of age may request their own Medicare card to access subsidized health care without their parents' involvement, though many are not aware of this. Prescriptions for low-income patients are further subsidized, making oral contraceptives relatively accessible. Nonetheless, for teenagers, the cost – and scariness – of condoms, doctors' visits, and prescriptions are a disincentive to contraceptive use, particularly in rural and remote areas where confidentiality is a problem.

The drop in the age of first intercourse is less significant to sexual risk patterns, however, than the rise in the age of marriage or entry into a long-term committed relationship. In the 1950s and 1960s, many people married the first or second person they had sex with (Cook, 2004). Nowadays this is rare, and young adults expect a decade or more of freedom and 'playing the field' before settling down. (This may also be affected by increasing housing unaffordability in cities; high home ownership among young couples, long a component of the 'Australian Dream', is now a thing of the past.) This change is reflected in the lower lifetime numbers of sexual partners reported by those currently in their 60s than those in their 30s, even though the older people have had longer in which to acquire them (de Visser et al., 2003b; unpublished ASHR2 data).

Australia's teenage birth rate in 2009, at 16.5 per 1000 girls of 15–19 years of age, was not as high as that in the UK (25) or the US (42), though considerably higher than Korea, China, Japan, Sweden, and Italy (3.5–6.8) (United Nations, 2013).

Indigenous Sexual Health

Demographically and politically, Australia is an immigrant country formed over the last 200 years, originally by British colonists and settlers, and carries the history of British law and institutions. Only about 2% of the population identifies as indigenous – Australian Aboriginal or Torres Strait Islander – and it is unclear how or to what degree indigenous sexual cultures have influenced mainstream Australian attitudes to sex. Precontact traditional Aboriginal societies were patriarchal and violent; women were promised in marriage, often in childhood, according to the rules of complex kinship patterns. William Buckley, an escaped convict who lived for years among the Aboriginals in the early nineteenth century, reports many of the violent skirmishes he witnessed among Aboriginals as being due to the escape or capture of a young woman by one group or another. It is arguable how much of this intergroup violence was partly produced by social disruption as a result of colonization.

Today's indigenous Australians have considerably worse health on average than the average Australian, resulting in markedly lower life expectancy. Sexual health is also worse, both in urban indigenous people and in rural settings. This disadvantage in sexual health is exacerbated by lack of health services in remote communities (Fairley et al., 1997).

High rates of casual sex – though with no higher numbers of partners than the general population – may put Aboriginal people at higher risk (Bryant et al., 2011). High mobility may also play a part in the epidemiology of STIs in Aboriginal communities (Hui et al., 2013). Consistent condom use in casual sex is low, but no lower than in the general population (Bryant et al., 2011).

It has also been argued that traditional health cultures of more remote Aboriginals, developed over millennia among naked, nomadic tribes, are not conducive to health in settled communities (Sutton, 2006). It is possible that traditional cultures involving separation of 'men's business' and 'women's business', notions of 'shame' and violent ways of dealing with emotional conflict, continue to affect Aboriginal sexual health,

especially women's health. Sexual and domestic violence, together with drug and alcohol problems, are serious issues for many Aboriginal communities (Arabena, 2006; Larkins et al., 2007).

Sex Work

Prostitution is treated differently by the law in each Australian state. Models vary from a decriminalized system to one where all sex work is illegal. Victoria has a system where some brothels are regulated and licensed, ensuring better working conditions and access to free condoms, but where many unlicensed brothels operate illegally and are difficult for outreach services and researchers to access. Decriminalization is associated with much better access by sexual health support services (Harcourt et al., 2010; Seib et al., 2009).

In NSW, the Sex Workers Outreach Project, operating under the auspices of the AIDS Council with funding from the state government, is a peer-run organization with staff (some of whom speak Asian languages) who have very good access to brothels of all types and to independent workers (Harcourt et al., 2010). Decriminalization has not been without its problems. In NSW, local authorities must authorize land use for all businesses, and some local councils have sought to refuse brothels planning permission on 'moral' grounds. Some businesses that are denied permission have continued to operate in breach of planning rules, and some have subsequently won cases in the Land and Environment Court appealing against council decisions (Julie Bates, Urban Realists, pers. comm.).

The Australian experience makes clear that legalizing sex work does not increase the size of the industry, which is driven by many factors such as client demand (not high in the general population in Australia, given the stigma of paying for sex and the ready availability of amateur sex), supply of potential workers (influenced by population levels of education, job availability, and immigration), and specific local needs such as high proportions of single men, for example in mining. About one man in six (15.6%) among men of 16–59 years of age said in the ASHR survey in 2001–02 that they had ever paid for sex, and only 1.9% had done so in the past year; rates by state did not suggest that illegality was a deterrent (Rissel et al., 2003d). The small size of the industry and the growing acceptability of sex work have led to better research, including research into clients. Unlike much of the research internationally, it does not assume that being a sex worker is necessarily both damaging and evidence of prior damage, not so much a job but a stigmatizing risk factor or poor health outcome in itself. Even though many sex workers have arrived in the industry with a history of sexual abuse, homelessness, or drug use, sex work can be a way of reclaiming agency in relations with men that is preferable to a self-image as a victim. Many of the dangers of sex work are direct results of its illegality, so that in criminalized settings workers cannot telephone the police if a client becomes violent, and are subject to police corruption such as demands for free services accompanied by threats of arrest.

The uneven but increasing respectability of sex work has led to attempts to make sexual services more readily available to people (usually men) who seek assistance because of illness or disability. At this specialized and professionalized end of the industry, there is an overlap between sex work and sexual surrogacy; some workers do both.

Homosexuality

Australia's pattern of social understandings of homosexuality is shared with countries of northwestern Europe. That is to say, attitudes to homosexuality and to gay men in particular are different from those around the Mediterranean, the middle East, Asia, Africa, and Latin America, in which men are more likely to be expected to marry women whatever their personal sexual tastes, and people think less of men who do not do so, and regard openly homosexual men as unmanly (Parker et al., 2000).

In Australia, at least among the educated middle class of largely Anglo-Celtic backgrounds, homosexuality is seen as primarily an issue of being attracted to people of the same sex. Educated people mostly regard gay men and lesbians as a variant of normal, just like heterosexuals except that they are attracted to people of the same sex. Thus two women in a same-sex relationship are both seen as lesbian and both men in a same-sex relationship are seen as gay, whether or not one of them is noticeably more dominant or masculine in manner and appearance.

Homosexuality is popularly regarded as an intrinsic element of personality, and as something one is born with, rather than as immorality or illness. Thus people's tolerance of same-sex acts and of homosexuality as identity or preference tends to overlap. In ASHR, 37% of men agreed that sex between adult men was always wrong, reflecting a lesser taboo on same-sex acts between women but only 21% that sex between adult women was always wrong. Among women, about a quarter disapproved of same-sex acts, whether between men or women (Rissel et al., 2003a).

Although not many same-sex-attracted people nowadays grow up imagining themselves to be the only one of their type, some (particularly in rural areas) may perceive that their only choices are either to join the flamboyant urban gay life of the Sydney Gay and Lesbian Mardi Gras (if they were accepted by the gay community) or to hide their feelings in order to be accepted by their peer groups. Over recent years, opportunities for making contact with potential sexual partners via the Internet and social media have reduced the cohesion of the gay community, which was once dependent upon gay community newspapers and venues in 'gay' districts. At the same time, the Internet and social media have made it easier for isolated young people to find out about others like themselves, to make contact with community groups, and to obtain health-related information.

Lesbians tend to be less visible to health and social policy than gay men, and face difficulties in getting their community needs met. For example, smoking rates are much higher among lesbians than other women, yet no community-specific smoking reduction or cessation programs have been run for lesbians (Mooney-Somers et al., 2012).

Despite the public and media attention given to homosexuality, there are more adult virgins than exclusive homosexuals (Smith et al., 2003b). Celibacy has been called the 'new deviancy' (Hart and Wellings, 2002), and this is probably also true in Australia.

Sexuality Over the Life Course

Abstract

This article focuses on the development of sexuality during childhood and how it is transformed over the life course. We discuss relevant findings from research on sexuality in childhood, through young adulthood and midlife, to older adulthood. We point to sexual scripts, the socially learned set of sexual desires and conduct, as a lens for understanding sexuality (*see* Scripts of Masculinity). We highlight life transitions and turning points, sexual agency, cumulative advantage and disadvantage, and the role of culture, gender, race, ethnicity, and social class in experiences of sexuality over the life course.

People continuously acquire and interpret emotional, physical, and intellectual experiences, which shape their lives in various ways. Events that occur early in life can directly or indirectly influence behavior and attitudes later. The environment in the home, race/ethnic background, social class, sexual identity, and religious beliefs have the potential to dramatically influence life trajectories (Carpenter and DeLamater, 2012). In turn, these factors and others shape sexuality over life stages, beginning at childhood and adolescence and continuing through menopause and old age.

Life transitions, either socially positive or negative, involve the movement from one social role to another. Major transitions that affect sexuality include sexual debut, cohabitation and marriage, the birth of children, relationship disruption, and the illness and death of one's spouse or partner (*see* Sexual Debut; Marital Quality and Health). These turning points have the potential to alter sexual attitudes, values, and behavior. The Gendered Sexuality over the Life Course (GSLC) Model, developed by Carpenter and DeLamater (2012) moves beyond life cycle stages to focus on the processes through which sexuality unfolds throughout life. This model will be used to highlight the interrelationships between different stages of sexual development. The GSLC model suggests a consideration of the impact of combinations of life transitions and experiences, either positive or negative. For example, sexual abuse as a child may act as a turning point and may interact with other experiences or transitions. Browning and Laumann (1997) showed that women who were sexually abused as children were more likely than nonabused children to have consensual sex before they were 16, bear children before 18, and contract sexually transmitted infections (*see* Sexually Transmitted Infections: Social Network Analysis). The authors conclude that each negative life transition reinforced negative sexual scripts learned from past experiences and redirected sexual trajectories; whereas, the positive transitions reduced disadvantages and sometimes created advantages for future choices.

Sexual Agency in a sociohistorical context is another key element of the GSLC model. Sexual agency describes how people attempt to shape their life trajectories in both the long term and short term to reflect their values and goals. Thus, a heterosexual single male who does not believe in waiting for marriage for sex enacts sexual agency by actively seeking sexual partners, whereas a woman who believes in waiting to have sex until marriage enacts sexual agency by declining his advances. *Sociohistorical context and generation*, both elements of the GSLC model, are important factors in sexual attitudes and behavior (Joyner and Laumann, 2001). The sexual and gender revolutions of the 1960s transformed sexual attitudes and behaviors, ushering in a period of liberal sexual values that led to earlier sexual debut, increases in unmarried childbearing, more frequent relationship turnover, and a wider variety of sexual practices than in previous generations (Das et al., 2012)

Childhood Sexuality

Although the life course of sexuality begins in childhood, most research has focused on adolescent and adult sexuality. Very little attention has been paid to normative or typical sexual behavior in young children (Thigpen, 2012). The literature that has focused on childhood sexuality puts a strong emphasis on adult–child sexual contact and sexual aggression in childhood. Many studies have found evidence of long-term social and emotional problems throughout life as a result of child–adult sexual contact. Child-to-child sexual aggression, abusive behavior that has both sexual and aggressive components committed by a child upon another child, has similar negative effects. It is thought that the majority of child-to-child aggressors are acting as a result of their own sexual victimization (Thigpen, 2012).

Normative Sexuality in Childhood

Recent studies of children aged 2–12 have expanded our knowledge of normative sexual behavior at younger ages. These studies show that, in early childhood, children typically engage in self-stimulatory behaviors, are interested in sexual topics, and show interest in viewing the genitals of the same and opposite sex. Genital manipulation and masturbatory behaviors are higher among boys than girls (Thigpen, 2012). As children become older, they develop physically, cognitively, and socially in ways that foster interest in and knowledge of sexual behavior. They also form and revise attitudes toward sex. Parenting behavior and attitudes affect those of children;

liberal parenting styles are associated with increased masturbation, higher frequency of touching parent's genitals, and increased overall sexual behavior (Thigpen, 2012). This highlights the importance of context for children's sexual behavior.

Cultural and Social Differences in Childhood Sexuality

Sexual behavior in childhood is shaped by biological, psychological, and social factors operating within specific cultural, social, and political contexts. Cross-cultural comparisons can reveal the effects of these contexts. Goldman and Goldman (1982) compared sexual knowledge among Australian, English, North American, and Swedish children aged 5–15. They found that Swedish children were most knowledgeable about sexuality, perhaps due to sexuality education in schools combined with permissive sexual beliefs and attitudes (*see* Sexuality Education). In the American context, sexual beliefs and attitudes have been shown to vary across socioeconomic, racial, and ethnic groups. African-American children tend to make their sexual debut at a younger age than white, Hispanic, or Asian children. They also tend to have higher rates of sex in adolescence and have more partners in adulthood than whites and Hispanic Americans (*see* Sexual Debut; Thigpen, 2012). Two large-scale studies compared the sexual behavior of African-American and white children aged 7–12 using the Child Sexual Behavior Inventory (CSBI), a parental report of child sexual behavior (Friedrich et al., 1991; Thigpen, 2009). The CSBI consists of 38 measures in 9 sexual behavioral domains. These domains include boundary problems, exhibitionism, gender role behavioral, self-stimulation, sexual anxiety, sexual interest, sexual intrusiveness/aggression, sexual knowledge, and voyeuristic behavior (Friedrich et al., 2001). Parents of white children reported that they displayed 19 sexual behaviors compared to 13 for African-American children. Self-stimulatory behaviors, consisting of genital touching and masturbation, were significantly more prevalent among white boys, whereas among African-American boys it was more common to signify an interest in sex or in girls, such as talking flirtatiously or wanting to watch nudity or sex on TV (Thigpen, 2012). White girls showed a broader range of behaviors and a higher prevalence of sexual behaviors. Self-stimulation and voyeuristic behavior, such as wanting to look at nude photos, was higher among white girls. African-American girls had a higher prevalence for wanting to watch movies that included nudity or sex (Thigpen, 2012).

Sexuality Development in Adolescence

Adolescence is an extremely important stage in the sexual life course (*see* Adolescent Sexual Risk). Biological and physiological changes occur rapidly during puberty, as do changes in/development of cognitive and social skills. During adolescence, boys and girls develop and hone their ability to analyze interpersonal relations and social organization. Most important, during adolescence children and teens gain an understanding of the social and cultural meaning of sexuality. They also acquire sexual scripts. Sexual debut may take place in adolescence or may be delayed until the late teens or young adulthood (*see* Sexual Debut). The timing of sexual debut is influenced by the adolescent's self-esteem, intentions, and drug use. Those who have low self-esteem tend to delay the onset of sexual behaviors. Likewise, teens who experiment with drugs and alcohol face an increased likelihood of early sexual debut (*see* Sexual Debut). Higher intelligence operates as a protective factor against early sexual activity during adolescence, and lower intelligence, to a point, is a risk factor. Higher intelligence is associated with postponement of the initiation of the full range of partnered sexual activities, from holding hands to intercourse (Halpern et al., 2000).

Physiological maturity affects the age at sexual debut; those with earlier age of menarche and spermarche tend to transition into partnered sexual behavior earlier than others (*see* Sexual Debut). Adolescent children are reaching sexual maturity at a much earlier age than their counterparts did a century ago, especially in the United States (Russell et al., 2012). Advances in nutrition and hygiene have contributed to this change. In the United States, public policy laws were established to limit adolescent sexual activity, as it is seen as a social problem. With adolescents becoming sexually mature and sexually active at earlier ages, much of the research on adolescent sexuality has focused on the attendant problems, such as violence, problems for emotional health, sexually transmitted infection, and pregnancy. Joyner and Udry (2000) compare change in levels of depression for adolescents with and without romantic involvement. They find that males and females who become romantically involved experience a larger increase in depression than their counterparts who do not; however, females experience an even larger increase in depression than males in response to romantic involvement. These results suggest that females' greater vulnerability to romantic involvement explains a large part of the emerging sex differences in depression during adolescence.

Sexual Agency

Learning to wield sexual agency is an important developmental task in adolescence. Adolescents must learn to negotiate affectionate and intimate relationships with appropriate others as part of a successful transition to adulthood. They must decide on and manage a sexual debut and all that sexuality entails. Sexual agency, the belief in one's ability to act upon sexual needs in a relationship, is an essential tool for adolescents and adults (Russell et al., 2012). In the United States, high rates of sexual assault, coercion, unintended pregnancies, and sexually transmitted infections may reflect an absence of sexual agency (Russell et al., 2012). The development of sexual agency is influenced by the social context in which it occurs, including the race, ethnicity, and social class of the individual.

Cultural and Social Differences in Adolescent Sexuality

Sexual trajectories through adolescence differ substantially by race, ethnicity, and social class. African-American females initiate partnered sex at an earlier average age than whites and Latina females. Asian-American teens are the most likely to delay sexual debut. Latina adolescents are, on average, 4 years younger than their partners. This is a larger age gap between partners than seen among adolescents of other races. Latino

and African-American adolescents are less likely than white teens to use contraceptives. The African-American population has the highest risk of sexually transmitted infections, HIV/AIDS, and pregnancies, compared to Latinos and white Americans (Russell et al., 2012). However, the birth rate for African-American girls aged 15–19 fell dramatically from 118 per 1000 in 1991 to 47 per 1000 in 2011, and is now about the same as the rate for Hispanic teens. Still, both African-American and Hispanic teens have birth rates about twice as high as those for white teens and four times as high as Asian teens (Martin et al., 2011). Sexual trajectories also vary widely across social and political contexts. Compared to German teens, American teens use contraceptives less, have higher rates of pregnancy, and have more abortions (Russell et al., 2012).

Social class also plays a major role in the sexual development and health of adolescents. Research on social class often focuses on the poor because it is believed that these adolescents are more sexually active and at a greater risk for negative consequences than are those from more privileged backgrounds. Tolman (2002) studied girls from urban environments who had experienced racism and poverty. He found that these girls felt less comfortable talking about their sexuality among peers and parents than girls from suburban areas. Also, the majority of teens who have contracted AIDS are from poor families, victimized prostitutes, or runaways (Russell et al., 2012). Adolescents from poor families use contraceptives less frequently, which can result in higher pregnancy rates. Girls from higher socioeconomic status families may also experience hardships related to sexuality in their adolescent years. For privileged adolescents, the strains of emerging sexuality tend to take different forms; the emphasis on being thin in upper-middle class communities may lead girls to develop a negative self-image, develop eating disorders, and become malnourished (Russell et al., 2012).

Adolescents are generally taught about the physical changes to expect during puberty and recommendations for healthy sexual behavior. Formal sexuality education is usually implemented through school curricula and may also be offered by religious institutions or community groups. However, most sexuality education is informal, occurring through interactions with parents, peers, or others, and through television, movies, print, and electronic media. Through these interactions, and with varying effectiveness, adolescents develop attitudes, values, ideas, sexual scripts, and sexual agency (*see* Sexuality Education). Sexuality education in schools in the United States often does not explicitly include information on contraception or about how to regulate sexuality in the presence of relationships.

Intersecting Trajectories: The Effect of Divorce on Adolescents

The sexual life course trajectories of parents intersect with those of their adolescent children to affect their attitudes and behavior. Adolescents whose parents divorced are more likely to approve of premarital intercourse than are adolescents whose parents remained together, a finding shown consistently in a meta-analysis study done by Jeynes (2006). The findings showed larger effects on positive attitudes toward premarital intercourse than on actual engagement in premarital intercourse (Jeynes, 2012). Research shows that parental divorce acts as a turning point in the sexual life course of children. Children of divorced parents are more likely to have children themselves prior to marriage, more likely to be unmarried and unpartnered as young adults, and more likely to divorce if married (McLanahan and Sandefur, 1994; Waite and Gallagher, 2000).

Sexualities from Young Adulthood through Midlife

College and Casual Sex

The transition from high school to college, especially for those students who move from the parental home to college housing, is a critical period for young adults to reconsider and perhaps change their sexual values and behavior (Wade and Heldman, 2012). For many college students, sex, drugs, alcohol, and partying are the dominant nonacademic activities (Wade and Heldman, 2012).

'Hooking up' is a term used to describe, among college students, a casual sexual encounter that does not always involve intercourse (*see* Hooking up and Casual Sex). These hookups may involve alcohol and may involve strangers, acquaintances, or friends. The casual aspect of hooking up allows college students to be sexually active without the burden of establishing a relationship or friendship (*see* Hooking up and Casual Sex; Taylor, 2013). Previous research has assumed that the men were pushing the hookup culture, but recent social critics have argued that female college students may perceive benefits from casual sex and freedom from the time demands of more serious relationships (Rosin, 2012). A study of 60 college women at the University of Pennsylvania found that most women are focused primarily, at least for the short term, on academic and professional goals. The hookup culture provides a way for these women to have a (casual) sex life without taking the time away from their studies (Taylor, 2013).

Consequences of Casual Sex

The hookup culture may come with substantial consequences, especially for young women. Many women report that their male partners' sexual pleasure is prioritized over their own. By hooking up, women are also taking the risk of being labeled negatively if they engage in casual sex with multiple partners (*see* Hooking up and Casual Sex). College students are more at risk of becoming victims of sexual assault than their peers not enrolled in college (Wade and Heldman, 2012). A study of 48 first-year students enrolled in a sexuality-related writing course provided insight into their sexual experiences. Many students reported that the transition from high school to freshman year was difficult. Some of the participants who were virgins upon starting college stated that they engaged in intercourse to 'fit in.' Other women reported that it was nearly impossible to have a cross-gender friendship because the men would only think about sex (Wade and Heldman, 2012).

Alcohol and parties form the cornerstone of the hookup scene. Alcohol removes one's inhibitions and often leads students to partake in uncharacteristic behavior that is directly opposed to their values and beliefs (Wade and Heldman, 2012). Parties create opportunities for sexualized dancing

and making out, which often lead to hooking up (*see* Hooking up and Casual Sex). Many students reported engaging in intercourse or oral sex because they were drunk. Even when sexual encounters were consensual, many of the students described the experience as unsatisfying. The male's pleasure was often prioritized over the female's, and many young men seemed to expect intercourse from every sexual encounter (Wade and Heldman, 2012).

Midlife Years and Older Adulthood

The period of the life course between adolescence and old age tends to be treated as homogenous 'midlife' when, in fact, many changes take place between ages 20 and 60. These years can include the establishment of stable partnerships, marriage, birth of children, career employment, as well as the loss of these roles through divorce, job loss, children leaving home, and changes in sexual function and behavior (Das et al., 2012). Trajectories of sexuality tend to diverge during midlife for men and women, and by social and cultural factors such as race and ethnicity. Trajectories are also affected by changes in partnership, the onset of chronic diseases, and, declines in physical, social, and cognitive functioning (Lindau et al., 2007; Laumann and Waite, 2008). Those who maintain an active sex life throughout these years tend to have better physical and emotional health and greater well-being (*see* Heterosexual Expression at Older Ages).

The availability of a partner through marriage or cohabitation is one of the chief predictors of sexual activity during the midlife stage. From age 18 to 35, women are more likely to have a stable partner than men, but after age 35, men are more likely to be partnered than women. Women aged 57–85 are less likely than men of their same age to be in a marital or other intimate relationship and this disparity increases dramatically with age. About 85% of men aged 57 are partnered compared to about 69% of women of the same age. By age 85, about 65% of men and only 29% of women are married or cohabitating. Among men and women of the same age, men with a spousal or other intimate relationship were more likely to be sexually active than women with such a relationship. This is due, in large measure, to the age difference between partners; men in their early 70s tend to be married to women in their mid-to-late 60s. Among the older adults who were not in a relationship, only 22% of men and 4% of women reported being sexually active in the previous year (Lindau et al., 2007).

The share of older adults who were sexually active in the past year declines with age, both among all adults and among those with a partner (*see* Heterosexual Expression at Older Ages). At ages 57–65, almost all partnered men and about 80% of partnered women were sexually active, but by ages 81–85 these numbers had fallen to about half of partnered men and 20% of partnered women (Lindau et al., 2007).

For sexually active adults aged 57–85, the frequency of sex was lower among those who were aged 75–85 among younger persons. However, even in this oldest age group, 54% of sexually active persons reported having sex at least two to three times per month, and 23% reported having sex once a week or more. Fifty-eight percent of sexually active people in the 57–64 age group reported engaging in oral sex, as compared with 31% in the 75–85 age group (Lindau et al., 2007).

The prevalence of masturbation, like that of sexual activity with a partner, was lower at older ages and was higher among men than among women. Poorer health was also associated with a lower likelihood of masturbation among women. Fifty-two percent of older men and 25% of older women with a spousal or other intimate relationship reported masturbating in the previous 12 months, as compared with 55% of older men and 23% of older women without a current spousal or other intimate relationship (Lindau et al., 2007).

Menopause, Infertility, and Miscarriage

Menopause, a major reproductive event and important turning point in the sexual life course of women, occurs on average between the ages of 48 and 52. Menopause is the cessation of menstruation caused by the fluctuation of hormones in the ovaries and bloodstream. Infertility is a direct result of menopause and can have major effects on the emotional well-being of women. The hormone fluctuations also can occur for several years prior to and after the onset of menopause (Dillaway, 2012). Hormone fluctuations and the end of fecundity can bring physical, psychological, and emotional changes and challenges.

Dillaway interviewed 98 women between the ages of 38 and 65 about their feelings pertaining to menopause and sexuality. Some women stated that they were relieved to be free of the risks of pregnancy and childbearing. Several participants stated that they felt relief from the cessation of menstruation. A sexual revitalization was also a common theme in the reports of postmenopausal women. One-third of the women in the study reported having had reproductive difficulties, such as miscarriages or infertility. These women reported having both a negative and positive outlook on menopause and their reproductive difficulties and these differed by race. The majority of the African-Americans stated that while miscarriages and abortions were emotionally devastating, they felt that they became emotionally stronger as a result. The white women who reported problems with pregnancy and childbearing more often stated that after infertility and miscarriages they were glad to reach menopause and move on. Women in this study who either married late or remarried often wanted to have children for their first time or with their new husbands. For them, menopause led to both reproductive problems and the accompanying emotional distress.

Physical Health and Sexuality

Physical health plays a major role in the ability to engage in sexual activity. Physical injuries, diabetes, cardiovascular disease, cancer, and medications for many chronic conditions may alter sexual trajectories at various points in the life course. The decrease in blood flow caused by cardiovascular disease or diabetes may lead to erectile dysfunction, as may treatments for prostate cancer. Some types of antidepressants also reduce sexual desire. Physical ailments such as arthritis and obesity can interfere with mobility and functional health, reducing capacity for sex and leading to sexual dysfunction (*see* Heterosexual Expression at Older Ages; Karraker and DeLamater, 2013).

In a study of older adults aged 57–85, women report their most prevalent sexual problems: 43% reported low sexual desire, 39% reported vaginal dryness, and 34% reported an inability to climax. For the men, erectile dysfunction affected 39 and 14% stated that they used medications or supplements to help with their sexual dysfunctions.

The success and popularity of medications for sexual dysfunction may redefine sexuality among older adults. In addition to alleviating sexual problems, the availability of these medications and the discussions about them in the media may reduce the negative stereotypes that surround the sexuality of older adults. In addition, demand for such medications may lead to future research on and development of treatments for other health issues connected to sexual dysfunction.

Mental health conditions also affect sexual activity and overall well-being. Anxiety, depression, bi-polar disorder, and stress tend to affect sexual interest and sexual activity adversely. Recent research has also shown that mental health conditions are more commonly associated with women's sexual problems than with men's (*see* Heterosexual Expression at Older Ages). It is important to note that the onset of a mental health problem might be associated with other underlying health issues, perhaps undiagnosed.

Living with Illnesses and Disabilities

Midlife may bring the onset of chronic disease and the associated loss of function and disability. The extent to which illness and disability are transitions in the life course depends on characteristics of the individual, their relationships and network of support, and the environment in which they live. In a study of men with spinal cord injuries, Bender (2012) examined the impact of this life course transition on the ability to establish and maintain sexual relationships. He concluded that financial status, social support, marital status, and age at occurrence were crucial determinants of men's ability to adapt to the situation.

Bender found that the participants' responses to disability could be grouped into four types: adaptation, performance, conformity, and relinquishment. The men who were in the adaptation group showed the highest levels of control over their sexual trajectories and satisfaction. These men tended to be young at the time of their injury, had high levels of education, and adequate financial security. They tended to be open about their sexual dysfunctions and limitations in relationships (Bender, 2012). The men in the performance group typically tried to present themselves as normal and unaffected by their disability. They felt able to pursue and end relationships on their own terms. Maintaining control over their sexual trajectories, they felt, allowed them to be viewed as desirable and emotionally stable to women they met (Bender, 2012). Unlike the adapters and performers, the conformers had low sexual agency and were older at the time of injury. These men found it difficult to understand their injury and how it would affect their current and future relationships. They tended to conform to the stereotype that older men with a disability cannot maintain a sexual relationship (Bender, 2012). The men in the relinquishment group had a fear of intimacy and tended to avoid dating and sex. These men lacked social support and financial security. They tended to have anxiety and fear about being able to perform sexually (Bender, 2012).

Sexuality in Later Life

Considerable attention has been paid to the onset of sexual activity in the early stages of the life course, and less to sexuality at older ages, including the cessation of partnered sex at older ages. Recent studies suggest that about a third of adults aged 57–85 have been sexually inactive for at least the last year. Karraker and DeLamater (2013) find that two thirds of these sexually inactive older adults believe their sexual relationships with their spouses are finished. For many of these individuals, this transition marks the end of their partnered sexual lives. Others may find a new partner after being widowed or divorced, or will resume a sexual relationship with a spouse who has recovered from a disability or illness.

Continued sexual involvement at older ages depends on the physical capacity to engage in sex, but recent research has shown that it is the health of the *husband* that matters; couples in which the wife is in poor health but the husband's health is good are much more likely to remain sexually active than couples in which the husband is in poor health but the wife's health is good.

Older adults who are happier with their marriage, and those who are remarried, tend to have sex more often than those in a first marriage or those who are less satisfied. This is also true at younger ages. Karraker and DeLamater (2013) find that although happier marriages tend to be sexually active marriages in midlife, at older ages this is less often the case; those in sexually inactive marriages are about as happy with their relationship as those who remain sexually active. Older adults in long-standing marriages may fall back on a lifetime of shared activities, shared children, and memories of an active sex life in the face of declining physical or cognitive function of one or both partners.

Sexuality, Theories of

Elke D Reissing and Heather VanZuylen, School of Psychology, University of Ottawa, Ottawa, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The purpose of this article is to provide a brief review of the historical origin of theories of human sexuality followed by a review of modern theories including sociobiological and evolutionary psychological theories, behaviorism, social learning theories, and cognitive theories. Next, social theories including social exchange theory, social constructionism, and script theory are examined. Last, theories which integrate multiple perspectives are discussed, such as biopsychosocial approaches and the dual control model of sexuality. The authors conclude that drawing on multiple, empirically validated theories provides the basis for researching and understanding complex and nuanced yet parsimonious explanations of sexuality.

The Importance of Theories

According to Larsen and Buss (2008), theories provide three useful tools for researchers. First, they provide a guide that helps determine the types of information that researchers should collect, the questions that are useful, and a direction for research. Secondly, theories organize previous findings and provide explanations for patterns in descriptive information. Finally, theories allow researchers to make predictions, which allow the testing of hypotheses. Larsen and Buss also provide standards to evaluate scientific theories, including comprehensiveness, testability, parsimony, and the steering of researchers toward making new discoveries. Scientific theories, therefore, need to accommodate and explain all relevant observations and be able to be falsified. Furthermore, they should be efficient at explaining observations with as few tenets as possible, lead researchers toward new lines of inquiry, and facilitate research in the field by integrating information from different sources into coherent concepts. As the different theories of sexuality are discussed, it is important to be mindful of the elements of genuine theories and the criteria by which they are evaluated. With the importance of theories in mind, early sexuality research will be discussed to provide a historical context to the diversity of contemporary theories that have developed over the past several decades.

Early Sexuality Research

Sexuality theories are relatively new, as sexuality has long been the domain of religion, morality, and philosophy rather than the sciences. The earliest scientific approaches to sexology were medical in nature, and thus early sexuality research was largely conducted by physicians and psychiatrists, particularly in Germany (Carroll, 2013). The medical model allowed for researchers to treat sexuality as a subdiscipline of biology and avoided some of the perceived stigma associated with sex. However, the medical model predominantly focused on sexual pathologies. During the 1800s, much of this research was summed up in *Psychopathia Sexualis* by Heinrich Kaan (1844), which was subsequently expanded upon by Richard von Krafft-Ebing (1886).

Not all early researchers were satisfied with the medical approach. Iwan Bloch founded the *Journal of Sexology* in 1914, in an attempt to draw on historical and anthropological accounts toward a broader understanding of sexual phenomena (Bullough, 1994). Some contemporaries of Bloch, such as Magnus Hirschfeld, Katharine Bement Davis, and Margaret Higgins Sanger used sexology research to foster social change, for example, to increase acceptance of homosexuality, female sexuality, masturbation, and birth control (Carroll, 2013).

Albert Moll published *Untersuchungen über die Libido sexualis*, the first psychological theory of sexuality, in 1897. He argued that the libido had two fundamental drives, *Detumeszenztrieb* (individualistic gratification) and *Contrectationstrieb* (intimacy with others). Although an open critic of Sigmund Freud, he shared Freud's belief that sexuality developed before puberty and that children had libidos (Bullough, 1994).

Although Freud had many contemporaries, his fame brought the psychology of sexuality to the forefront. Freud (1924; see also Petersen and Hyde, 2010) proposed a 'stage model,' whereby the libido was focused on different erogenous zones throughout childhood and these stages, (the oral, anal, phallic, latent, and genital stages) had to be successfully resolved; otherwise individuals could develop fixations and maladaptive personality traits in adulthood. Although criticized for being untestable, sexist, heterosexist, and based on information from only nonnormative case studies (Petersen and Hyde, 2010; Nelson, 2010), Freud's theories have given rise to more contemporary theories, such as feminist psychoanalysis (e.g., Chodorow, 1989) and the object-relations theory (Person, 1980).

Although not all aspects of these historical theories are currently accepted, it is important to acknowledge the work of these pioneers as they laid the foundations of modern sexology and sexual theory. In the remainder of the article, modern theories including biological, learning, cognitive, sociological, and integrated theories will be discussed with regard to their pioneers, basic tenets, examples of seminal research, and predominant critiques.

Sociobiology and Evolutionary Psychology

This theoretical perspective examines the biological causes of behavior, including the use of animal models, genetic analyses, and the study of hormones and neurological substrates (Wilson, 1978). Evolutionary psychology applies the forces of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.35030-9

evolution and natural selection to social behaviors and proposes that certain behaviors are maintained because they are adaptive to the reproductive success of an organism or genetically similar organisms (Confer et al., 2010). In humans, particular ancestral behaviors allowed humans to survive and raise more viable children; therefore the biological bases for that behavior were inherited, thus increasing the frequency of those genes and behaviors (Roberts, 2012). Evolutionary psychology has been applied to a number of human sexual behaviors, including the preference for monogamy and coparenting (a rarity in mammals), which are linked to an increase in receptor sites and activity of the neurotransmitters, oxytocin, and vasopressin (Fisher, 2012). It has also been applied to sex offenders and the adaptive potential of rape (Camilleri, 2012; see also Buntin, this work, for more information on sexual violence), and gender differentiated popularity of romance novels and pornography (Salmon, 2012).

At the core of many evolutionary insights into sexuality is the Sexual Strategies Theory (SST; Buss, 1998), which asserts that there are two main mating strategies, short-term and long-term. Ancestrally, reproduction involved a higher cost for females who are burdened with pregnancy and nursing, compared to the minimal cost involved for men in the donation of sperm. Therefore the primary mating strategy of women is long-term (i.e., forming a long-term relationship), as it is in a female's best interest to carefully choose a partner with resources, who is interested in contributing to raising their child. For a man, a risk of this long-term strategy is that he may be investing resources in a child who is not genetically related. Therefore, men have a greater interest in short-term mating strategies (i.e., casual sex) than women, as this increases the number of potential children (see England & Ronen, this work, for more information on casual sex). However, having greater interest in casual sex does not negate the ability for men to form long-term relationships and raise children, as this strategy maximizes the chances of survival for the child.

Hypotheses generated by this theory have received some support. For example, based on SST, men and women respond differently to various types of infidelity in heterosexual relationships. Women show greater concern if their partner is emotionally attracted to another woman (potentially investing in her); while men show significantly more concern if the partner is physically attracted to another man (potentially unfaithful); (Sabini, 2004; *see* Heterosexual Sexuality: Partner Bond Formation, Sexual Attitudes, Sexual Practices, and Sexual Function over the Life Course).

Evolutionary psychology and sociobiology have been criticized as emphasizing the need to understand ancestral conditions in order to predict presumably more complex, current behaviors. Yet many of the predictions and findings of evolutionary psychology are in fact in line with more proximal theories, such as social and learning theories (Gannon, 2002). Some have argued that the distal causes of behavior are not testable and are less relevant than observable social- and cognitive-based hypotheses (Deaux, 1999). Additionally, when results contradict the evolutionary paradigm, they are sometimes dismissed with the explanation that current conditions differ from ancestral ones (Gannon, 2002). Other theorists have criticized the idea that much of humans' past involved constancy in sexuality and mating choices (Foucault, 1978). Despite these criticisms, evolutionary psychology continues to be a burgeoning field with rich explanatory power, especially when studied as basic predispositions in conjunction with theories that take the social environment into account.

Behaviorism

Behaviorism is the study of how behaviors come about in response to stimuli in the environment, particularly the study of processes associating outcomes with different stimuli through operant or classical conditioning. Behaviorists consider the mind of the child as a blank slate with a few inborn abilities aimed at basic survival and the ability to learn through association (Allgeier and Allgeier, 1998). Thus, people are highly malleable by the environment. *Operant conditioning*, pioneered by Skinner (1974), proposes that behaviors become more frequent when reinforced and diminish when punished. Rewards that satisfy biological or intrinsic needs, such as sex, are primary reinforcers. Thus, behaviors that lead to sex or sexual pleasure will become more frequent and behaviors that interfere with obtaining sex will diminish. Notably, sex is both a behavior and a reinforcer, indicating that sexuality has both innate and learned qualities. For example, when young children might play with their genitals in front of a parent and this behavior may be punished. Thus the young person learns what is sexually pleasurable but also learns to restrict this activity to socially acceptable situations (Allgeier and Allgeier, 1998). Operant conditioning has been used to explain some cases of compulsive sexual behavior; for example, someone who persistently uses sexual behavior to cope with stress is engaging in an intrinsically rewarding activity, while also relieving a negative emotional state, which is also rewarding. This can lead to a positive feedback cycle that increases sexual activity until it may become uncontrollable (Carnes, 1983).

Classical conditioning was developed by Pavlov, who observed that after repeatedly pairing a stimulus that did not elicit a response (neutral stimulus) with a stimulus that did cause a response (unconditioned stimulus; unconditioned response), a link between the two stimuli was formed, such that the neutral stimulus (now a 'conditioned' stimulus) presented on its own, could elicit the same response as the unconditioned stimulus (conditioned response). Thus the association from one stimulus can be transferred to another through repeated pairing; for example, the smell of a lover's perfume or cologne may become arousing through repeated pairings of sexual interest and the odor (Allgeier and Allgeier, 1998). In a similar manner, an aversive stimuli experienced during sexual arousal can lead to a decrease in sexual responses, even when the aversive stimulus is removed (Both et al., 2008). Classical conditioning has been used to explain some of the complexities of sexuality, such as having fetishes or sexual phobias. For example, in therapy, systematic desensitization was used to help patients to disentangle negative associations with sex. The opposite process was used to try to reduce patients' atypical or problematic sexual attractions (Hogben and Byrne, 1998). Despite being empirically supported, learning theories were somewhat limited and did not necessarily capture the full range of human sexuality. Social learning

theory emerged to account for observational learning, values, cognitions, and social interactions.

Social Learning Theory

Social Learning Theory was popularized by Bandura (1986), and encompasses how observations in the social world impact behaviors and cognitions. Although classical and operant conditioning are still relevant, Bandura also proposed modeling, where an observer views a person's actions and their consequences. If that person is rewarded, the observer is more likely to mimic those actions. However, if the action is punished, the observer learns to expect negative consequences from that behavior. Modeling may take place immediately (direct imitation) or the consequences of the behavior are remembered later (observational learning) (Nelson, 2010). For example, premarital sex may be rewarded in some communities and punished in others; and by observing these consequences, members of these communities learn the expectations of acceptable sexual behavior. In fact, the belief that peers are also sexually active is a strong predictor of previous engagement in sexual activity (Christopher et al., 1993; *see* Sexual Debut). Thus, socialization, culture, and media contribute to the development of expectations of the consequences of behaviors and one does not need to experience reinforcement or punishment personally in order to be affected. Bandura (1977) proposed that after successfully performing a task, one experiences a sense of self-efficacy. In the sexual context, the affective experience and timing of first intercourse may be of particular importance, as it has a strong impact on sexual self-efficacy, which is positively correlated with healthy sexual adjustment in later life (Reissing et al., 2011, 2005).

Although heavily supported through empirical research, the primary criticisms of the social learning theory include that it assumes passivity in the nature of the observer who recieves rewards or punishments, that the theory does not explain why certain behaviors are rewarded or punished, and that it fails to explain why some individuals will not conform to social norms (Nelson, 2010). The following theories will address some of these concerns.

Cognitive Theories
